

# FOUNDATIONS OF DATABASES AND QUERY LANGUAGES

**Lecture 13: Graph Databases and Path Queries** 

Markus Krötzsch

TU Dresden, 13 July 2015

Review: Datalog

Datalog is a powerful recursive query language

#### Advantages:

- Natural extension of (U)CQs with recursion
- Can be extended with (EDB) negation
- Polynomial data complexity of query answering

#### Disadvantages:

- $\bullet$  High query and combined complexity (ExpTime)
- Perfect optimisation is undecidable
- Somewhat complicated to write gueries

#### Overview

- 1. Introduction | Relational data model
- 2. First-order queries
- 3. Complexity of query answering
- 4. Complexity of FO query answering
- 5. Conjunctive queries
- 6. Tree-like conjunctive queries
- 7. Query optimisation
- 8. Conjunctive Query Optimisation / First-Order Expressiveness
- 9. First-Order Expressiveness / Introduction to Datalog
- 10. Expressive Power and Complexity of Datalog
- 11. Optimisation and Evaluation of Datalog
- 12. Evaluation of Datalog (2)
- 13. Graph Databases and Path Queries
- 14. Outlook: database theory in practice

See course homepage [⇒ link] for more information and materials

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 2 of 29

## Graph Databases

Our original motivation for going from FO queries to Datalog: Reachability of nodes in a (directed) graph  $\rightarrow$  let's focus on graphs

Graph database: a DBMS that supports "graphs" as its datamodel

There are many kinds of graphs:

- Directed or undirected?
- Labelled or unlabelled edges/nodes?
- What kinds of labels? Datatypes?
- Parallel edges (multi-graphs)? With same label?
- One graph or several graphs per database?

Two types of graph database models dominate the market today: Resource Description Framework (RDF) and Property Graph

## Resource Description Framework (RDF)

#### RDF is a W3C standard for representing linked data on the Web

- Directed labelled graph; nodes are identified by their labels
- Labels are URIs or datatype literals
- Multiple parallel edges only when using different edge labels
- Supports multiple graphs in one database
- W3C standard; implementations for many programming languages
- Datatype support based on W3C XML Schema datatypes
- Graphs can be exchanged in many standard syntax formats

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 5 of 29

## Representing Graphs

#### Graphs (of any type) are usually viewed as sets of edges

- RDF: triples of form subject-predicate-object
  - When managing multiple graphs, each triple is extended with a fourth component (graph ID) → quads
  - RDF databases are sometimes still called "triple stores", although most modern systems effectively store quads
- Property Graph: edge objects with attribute lists
  - represented by Java objects in Blueprints

#### Graphs can be stored in relational databases

- RDF: table Triple[Subject, Predicate, Object]
- Property Graph: tables Edge[Sourceld, Edgeld, Targetld] and Attributes[Id, Attribute, Value]

## **Property Graph**

#### Property Graph is a popular data model of many graph databases

- Directed labelled multi-graph; labels do not identify nodes
- "Labels" can be lists of attribute-value pairs
- Multiple parallel edges with the exact same labels are possible
- No native multi-graph support (could be simulated with additional attributes)
- No standard definition of technical details; most common implementation: Tinkerpop/Blueprints API (Java)
- Datatype support varies by implementation
- No standard syntax for exchanging data

Markus Krötzsch, 13 July 2015

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 6 of 29

## Representing Data in Graphs

#### Property Graphs can represent RDF:

- use attributes to store RDF node and edge labels (URIs)
- use key constraints to ensure that no two distinct nodes can have same label

#### RDF can represent Property Graphs:

- use additional nodes to represent Property Graph edges
- use RDF triples with special predicates to represent attributes

Either model can also represent hypergraphs/RDBs (exercise)

- → all models can represent all data in principle
- → supported guery features and performance will vary

## Querying Graphs

Preferred query language depends on graph model

- RDF: W3C SPARQL query language
- Property Graph: no uniform approach to data access
  - many tools prefer API access over a query language
  - proprietary query languages, e.g., "Cypher" for Neo4j

However, there are some common basics in almost all cases:

- Conjunctive queries
- Regular path queries

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 9 of 29

## Regular Path Queries

Idea: use regular expressions to navigate over paths

Let's consider a simplified graph model, where a graph is given by:

- Set of nodes *N* (without additional labels)
- Set of edges E, labelled by a function  $\lambda : E \to L$ , where L is a finite set of labels

#### Definition

A regular expression over a set of labels *L* is an expression of the following form:

$$E ::= L \mid (E \circ E) \mid (E + E) \mid E^*$$

A regular path query (RPQ) is an expression of the form E(s, t), where E is a regular expression and s and t are terms (constants or variables).

## Conjunctive Queries over Graphs

Basic descriptions of local patterns in a graph

Formally, it suffices to say:

CQs over RDF correspond to CQs over relational databases with a single table Triple[Subject, Predicate, Object]

(analogously for Property Graphs)

- All complexity results for query answering and optimisation carry over from RDBs (in particular, restricting to graphs does not make anything simpler)
- Details of representation of data in tables do not matter
- CQs are restricted to local patterns (no reachability . . . )

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 10 of 29

## Semantics of Regular Path Queries

As usual, a regular expression E matches a word  $w = \ell_1 \cdots \ell_n$  if any of the following conditions is satisfied:

- $E \in L$  is a label and w = E.
- $E = (E_1 \circ E_2)$  and there is  $i \in \{0, ..., n\}$  such that  $E_1$  matches  $\ell_1 \cdots \ell_i$ and  $E_2$  matches  $\ell_{i+1}\cdots\ell_n$  (the words matched by  $E_1$  and  $E_2$  can be empty if i = 0 or i = n, respectively).
- $E = (E_1 + E_2)$  and w is matched by  $E_1$  or by  $E_2$
- $E = E_1^*$  and w has the form  $w_1 w_2 \cdots w_m$  for  $n \ge 0$ , where each word  $w_i$ is matched by  $E_1$

#### Definition

Let a and b be constants and x and y be variables. An RPQ E(a, b)is entailed by a graph G if there is a directed path from node a to node b that is labelled by a word matched by E. The answers to RPQs E(x, y), E(x, b), and E(a, y) are defined in the obvious way.

## Extending the Expressive Power of RPQs

Regular path queries can be used to express typical reachability queries, but are still quite limited → extensions

#### 2-Way Regular Path Queries (2RPQs)

- For every label  $\ell \in L$ , also introduce a converse label  $\ell^-$
- Allow converse labels in regular expressions
- Matched paths can follow edges forwards or backwards

#### Conjunctive Regular Path Queries (CRPQs)

- Extend conjunctive queries with RPQs
- RPQs can be used like binary query atoms
- Obvious semantics

Conjunctive 2-Way Regular Path Queries (C2RPQs) combine both extensions

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 13 of 29

## Complexity of RPQs

A nondeterministic algorithm for Boolean RPQs:

- Transform regular expression into a finite automaton
- Starting from the first node, guess a matching path
- When moving along path, advance state of automaton
- Accept if the second node is reached in an accepting state
- $\bullet\;$  Reject if path is longer than size of graph  $\times$  size of automaton

Space requirements when assuming query (and automaton) fixed: pointer to current node in graph, pointer to current state of automaton, counter for length of path  $\rightsquigarrow$  NL algorithm

Conversely, reachability in an unlabelled graph is hard for  $\rm NL \sim RPQ$  matching is  $\rm NL\textsubscript{-}complete$  (data complexity)

(Combined/query complexity is in P, as we will see below)

C2RPQs: Examples

All ancestors of Alice:

 $((father + mother) \circ (father + mother)^*)(alice, y)$ 

People with finite Erdös number:

(authorOf  $\circ$  authorOf $^-$ )\*(x, paulErdös)

Pairs of stops connected by tram lines 3 and 8:

 $(\text{nextStop3} \circ \text{nextStop3}^*)(x, y) \land (\text{nextStop8} \circ \text{nextStop8}^*)(x, y)$ 

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 14 of 29

## Complexity of C2RPQs

We already know:

- CQ matching is in  $AC^0$  (data complexity) and NP-complete (query and combined complexity)
- $\bullet \ \ \mathsf{RPQ} \ \mathsf{matching} \ \mathsf{is} \ \mathrm{NL}\text{-}\mathsf{complete} \ \mathsf{(data)} \ \mathsf{and} \ \mathsf{in} \ \mathrm{P} \\ \mathsf{(query/combined)} \\$
- $AC^0 \subset NL$  and  $NL \subseteq NP$

 $\sim$  C2RPQs are NP-hard (combined/query) and NL-hard (data)

It's not hard to show that these bounds are tight:

#### Theorem

Markus Krötzsch, 13 July 2015

C2RPQ matching is  $\rm NP\text{-}complete$  for combined and query complexity, and  $\rm NL\text{-}complete$  for data complexity.

## (C2)RPQs and Datalog

How do path queries relate to Datalog?

We already know:

- Datalog is ExpTime-complete (combined/query) and P-complete (data)
- C2RPQs are NP-complete (combined/query) and NL-complete (data)

→ maybe Datalog is more expressive that C2RPQs . . .

Indeed, we can express regular expressions in Datalog

For simplicity, assume that we have a binary EDB predicate  $p_{\ell}$  for each label  $\ell \in L$  (other encodings would work just as well)

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 17 of 29

## Reprise: Combined Complexity of 2RPQs

As a side effect, the previous translation shows that 2RPQs can be evaluated in P combined complexity:

- Each (2-way) regular expression E leads to a Datalog query  $\langle Q_E, P_E \rangle$  of polynomial size
- Each rule in  $P_E$  has at most three variables  $\sim$  the grounding of  $P_E$  for a graph with nodes N is of size  $|P_E| \times |N|^3$
- propositional logic rules can be evaluated in polynomial time

ightarrow polynomial time decision procedure

## 2-Way Regular Expressions in Datalog

We transform a regular expression E to a Datalog query  $\langle Q_E, P_E \rangle$ :

If 
$$E = \ell \in L$$
 is a label, then  $P_E = \{Q_E(x, y) \leftarrow p_{\ell}(x, y)\}$ 

If  $E = \ell^-$  is the converse of a label  $\ell \in L$ , then

$$P_E = \{ \mathsf{Q}_E(x, y) \leftarrow \mathsf{p}_\ell(y, x) \}$$

If  $E = (E_1 \circ E_2)$  then

$$P_E = P_{E_1} \cup P_{E_2} \cup \{Q_E(x, z) \leftarrow Q_{E_1}(x, y) \land Q_{E_2}(y, z)\}$$

If  $E = (E_1 + E_2)$  then

$$P_E = P_{E_1} \cup P_{E_2} \cup \{Q_E(x, y) \leftarrow Q_{E_1}(x, y), Q_E(x, y) \leftarrow Q_{E_2}(x, y)\}$$

If  $E = E_1^*$  then

$$P_E = P_{E_1} \cup \{ \mathsf{Q}_E(x, x) \leftarrow, \mathsf{Q}_E(x, z) \leftarrow \mathsf{Q}_E(x, y) \land \mathsf{Q}_{E_1}(y, z) \}$$

Foundations of Databases and Query Languages

slide 18 of 29

## Expressing C2RPQs in Datalog

It is now easy to express C2RPQs in Datalog:

- Use the encoding of CQs in Datalog as shown in the exercise
- Express 2RPQ atoms in Datalog as just shown

Can every Datalog query over binary "labelled-edge" EDB predicates be expressed with (C2)RPQs?

- This would imply P = NL (but not that NP = ExpTime!): unlikely but not known to be false
- However, there are stronger direct arguments that show the limits of C2RPQs (exercise)

## Linear Datalog and Binary Datalog

Expressing 2RPQs in Datalog requires only restricted forms of Datalog:

#### Definition

A Datalog program is linear if each of its rules has at most one IDB atom in its body. A Datalog program is binary if all of its IDB predicates have arity at most two.

The following complexity results are known:

#### **Theorem**

Query answering in linear Datalog is  $\rm NL$ -complete for data complexity, and  $\rm PSPACE$ -complete for combined and query complexity.

Combined complexity further drops to NP for binary Datalog.

→ complexity results that are more similar to (C2)RPQs . . .

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 21 of 29

## Linear Datalog vs. 2RPQs

So all 2RPQs can be expessed in linear Datalog Is the converse also true?

No. Counterexample:

Query
$$(x, z) \leftarrow p_a(x, y) \land p_b(y, z)$$
  
Query $(x, z) \leftarrow p_a(x, x') \land Query(x', z') \land p_b(z', z)$ 

The linear Datalog program matches paths with labels from  $a^nb^n$   $\rightarrow$  context-free, non-regular language  $\rightarrow$  not expressible in (C2)RPQs

Intuition: linear Datalog generalises context-free languages

## 2RPQs and Linear Datalog

The Datalog translation of 2RPQs does not lead to linear Datalog, but we can fix this.

We transform a regular expression E to a linear Datalog query  $\langle Q_E, P_E^{lin} \rangle$ :

- Construct a non-deterministic automaton  $\mathcal{A}_E$  for E
- For every state q of  $\mathcal{A}_E$ , we use a binary IDB predicate  $S_q$
- For the starting state  $q_0$  of  $\mathcal{A}_E$ , we add a rule  $S_{q_0}(x,x) \leftarrow$
- For every transition  $q \stackrel{\ell}{\to} q'$  of  $\mathcal{A}_E$ , we add a rule

$$S_{q'}(x, z) \leftarrow S_q(x, y) \wedge p_{\ell}(y, z)$$

• For every final state  $q_f$  of  $\mathcal{R}_E$ , we add a rule

$$Q_E(x, y) \leftarrow S_{q_f}(x, y)$$

Two-way queries can be captured by allowing two-way transitions.

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 22 of 20

## Query Optimisation for C2RPQs

Recall the basic static optimisation problems of database theory:

- Query containment
- Query equivalence
- Query emptiness

Markus Krötzsch, 13 July 2015

Which of these are decidable for (C2)RPQs?

Observation: query emptiness is trivial

#### Containment for RPQs

Containment of Regular Path Queries corresponds to containment of regular expressions  $\sim$  known to be decidable in PSPACE

Proof sketch for checking  $E_1 \sqsubseteq E_2$ :

- (1) Construct non-deterministic automata (NFAs),  $A_1$  and  $A_2$  for the regular expressions  $E_1$  and  $E_2$ , respectively
- (2) Construct an automaton  $\bar{A}_2$  that accepts the complement of  $A_2$ .
- (3) Construct the intersection  $A_1 \cap \bar{A}_2$  of  $A_1$  and  $\bar{A}_2$
- (4) Check if  $A_1 \cap \bar{A}_2$  accepts a word (if yes, then there is a counterexample that disproves  $E_1 \sqsubseteq E_2$ ; if no, then the containment holds)

#### Complexity estimate:

 $A_1 \cap \bar{A}_2$  is exponential (blow-up by powerset construction in step (2)) but step (4) is possible by checking reachability on the state graph

- → NL algorithm on an exponential state graph
- $\rightarrow$  NPSPACE algorithm (construct the state graph on the fly)
- → PSPACE algorithm (Savitch's Theorem)

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 25 of 29

## Query Optimisation for Path Queries

Decidable in PSPACE (2RPQs) and EXPSPACE (C2RPQs)

Should be compared to linear Datalog:

#### **Theorem**

Query containment for linear Datalog queries is undecidable.

Proof: see Lecture 11 (Post Correspondence Problem in Datalog – in fact, in linear Datalog)

Essentially no adoption in practice

- → maybe the complexities are too high . . .
- → or maybe path query optimisers are just too primitive

## Containment for (C)2RPQs

Things are more tricky when adding converses and conjunctions

#### **Theorem**

- Containment of 2RPQs is PSPACE-complete
- Containment of C2RPQs is ExpSpace-complete

The proofs are more involved.

Automata-theoretic constructions are used, but with more complicated automata models and for somewhat different languages (there is no good "language of possible C2RPQ matches on a graph" → consider language of possible proofs instead)

Markus Krötzsch, 13 July 2015

Foundations of Databases and Query Languages

slide 26 of 29

## Path Queries: Final Remarks on Expressivity

We have seen that C2RPQs are NL-complete for data → can all NL-complete gueries be captured by a C2RPQ?

No. For many reasons.

Markus Krötzsch. 13 July 2015

- C2RPQs have no disjunction (→ Unions of C2RPQs)
- C2RPQs have no negation

FO-queries with a binary transitive closure operator capture NL

#### Several (regular) extensions of path queries:

- Nested unary 2RPQs in regular expressions ("test operators")
- Nested binary C2RPQs in regular expressions
- Other more expressive fragments of "regular Datalog", e.g., Monadically Defined Queries

## Summary and Outlook

Graph databases as an important class of "noSQL" databases

#### Two main data models

- Resource Description Framework (RDF)
- Property Graph

#### Path queries as common foundation of all graph query languages

- higher data complexities than CQs/FO queries
- lower complexities than Datalog queries
- decidable query optimisation

#### Next topics:

- Applications
- Summary

Markus Krötzsch, 13 July 2015
