

## DATABASE THEORY

#### Lecture 10: Conjunctive Query Optimisation

Markus Krötzsch

**Knowledge-Based Systems** 

TU Dresden, 10th May 2022

More recent versions of this slide deck might be available. For the most current version of this course, see https://iccl.inf.tu-dresden.de/web/Database\_Theory/en

#### Review

# There are many well-defined static optimisation tasks that are independent of the database

→ query equivalence, containment, emptiness

Unfortunately, all of them are undecidable for FO queries  $\sim$  Slogan: "all interesting questions about FO queries are undecidable"

 $\rightsquigarrow$  Let's look at simpler query languages

### Optimisation for Conjunctive Queries

Optimisation is simpler for conjunctive queries

Example 10.1: Conjunctive query containment: $Q_1$ : $\exists x, y, z. R(x, y) \land R(y, y) \land R(y, z)$  $Q_2$ : $\exists u, v, w, t. R(u, v) \land R(v, w) \land R(w, t)$  $Q_1$  find *R*-paths of length two with a loop in the middle $Q_2$  find *R*-paths of length three $\rightsquigarrow$  in a loop one can find paths of any length $\rightsquigarrow Q_1 \sqsubseteq Q_2$ 

### Deciding Conjunctive Query Containment

Consider conjunctive queries  $Q_1[x_1, \ldots, x_n]$  and  $Q_2[y_1, \ldots, y_n]$ .

**Definition 10.2:** A query homomorphism from  $Q_2$  to  $Q_1$  is a mapping  $\mu$  from terms (constants or variables) in  $Q_2$  to terms in  $Q_1$  such that:

- $\mu$  does not change constants, i.e.,  $\mu(c) = c$  for every constant c
- $x_i = \mu(y_i)$  for each i = 1, ..., n
- if Q<sub>2</sub> has a query atom R(t<sub>1</sub>,..., t<sub>m</sub>) then Q<sub>1</sub> has a query atom R(μ(t<sub>1</sub>),...,μ(t<sub>m</sub>))

### Deciding Conjunctive Query Containment

Consider conjunctive queries  $Q_1[x_1, \ldots, x_n]$  and  $Q_2[y_1, \ldots, y_n]$ .

**Definition 10.2:** A query homomorphism from  $Q_2$  to  $Q_1$  is a mapping  $\mu$  from terms (constants or variables) in  $Q_2$  to terms in  $Q_1$  such that:

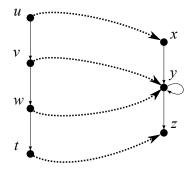

- $\mu$  does not change constants, i.e.,  $\mu(c) = c$  for every constant c
- $x_i = \mu(y_i)$  for each i = 1, ..., n
- if Q<sub>2</sub> has a query atom R(t<sub>1</sub>,...,t<sub>m</sub>) then Q<sub>1</sub> has a query atom R(µ(t<sub>1</sub>),...,µ(t<sub>m</sub>))

**Theorem 10.3 (Homomorphism Theorem):**  $Q_1 \subseteq Q_2$  if and only if there is a query homomorphism  $Q_2 \rightarrow Q_1$ .

#### $\rightarrow$ decidable (only need to check finitely many mappings from $Q_2$ to $Q_1$ )

#### Example

#### Review: CQs and Homomorphisms

If  $\langle d_1, \ldots, d_n \rangle$  is a result of  $Q_1[x_1, \ldots, x_n]$  over database I then:

- there is a mapping  $\nu$  from variables in  $Q_1$  to the domain of  $\mathcal{I}$
- $d_i = v(x_i)$  for all i = 1, ..., n
- for all atoms R(t<sub>1</sub>,...,t<sub>m</sub>) of Q<sub>1</sub>, we find ⟨v(t<sub>1</sub>),...,v(t<sub>m</sub>)⟩ ∈ R<sup>I</sup> (where we take v(c) to mean c for constants c)

 $\rightsquigarrow \mathcal{I} \models Q_1[d_1, \dots, d_n]$  if there is such a homomorphism  $\nu$  from  $Q_1$  to  $\mathcal{I}$ 

(Note: this is a slightly different formulation from the "homomorphism problem" discussed in a previous lecture, since we keep constants in queries here)

#### Proof of the Homomorphism Theorem

"⇐":  $Q_1 \sqsubseteq Q_2$  if there is a query homomorphism  $Q_2 \rightarrow Q_1$ .

- (1) Let  $\langle d_1, \ldots, d_n \rangle$  be a result of  $Q_1[x_1, \ldots, x_n]$  over database I.
- (2) Then there is a homomorphism  $\nu$  from  $Q_1$  to I.
- (3) By assumption, there is a query homomorphism  $\mu : Q_2 \rightarrow Q_1$ .
- (4) But then the composition ν ∘ μ, which maps each term t to v(μ(t)), is a homomorphism from Q<sub>2</sub> to I.
- (5) Hence  $\langle v(\mu(y_1)), \dots, v(\mu(y_n)) \rangle$  is a result of  $Q_2[y_1, \dots, y_n]$  over I.
- (6) Since  $v(\mu(y_i)) = v(x_i) = d_i$ , we find that  $\langle d_1, \ldots, d_n \rangle$  is a result of  $Q_2[y_1, \ldots, y_n]$  over *I*.

Since this holds for all results  $\langle d_1, \ldots, d_n \rangle$  of  $Q_1$ , we have  $Q_1 \sqsubseteq Q_2$ .

(See board for a sketch showing how we compose homomorphisms here)

Markus Krötzsch, 10th May 2022

Database Theory

### Proof of the Homomorphism Theorem

" $\Rightarrow$ ": there is a query homomorphism  $Q_2 \rightarrow Q_1$  if  $Q_1 \sqsubseteq Q_2$ .

- (1) Turn  $Q_1[x_1, \ldots, x_n]$  into a database  $\mathcal{I}_1$  in the natural way:
  - The domain of  $I_1$  are the terms in  $Q_1$
  - For every relation *R*, we have  $\langle t_1, \ldots, t_m \rangle \in R^{\mathcal{I}_1}$  exactly if  $R(t_1, \ldots, t_m)$  is an atom in  $Q_1$
- (2) Then  $Q_1$  has a result  $\langle x_1, \ldots, x_n \rangle$  over  $I_1$

(the identity mapping is a homomorphism - actually even an isomorphism)

- (3) Therefore, since  $Q_1 \sqsubseteq Q_2$ ,  $\langle x_1, \ldots, x_n \rangle$  is also a result of  $Q_2$  over  $I_1$
- (4) Hence there is a homomorphism v from  $Q_2$  to  $I_1$
- (5) This homomorphism  $\nu$  is also a query homomorphism  $Q_2 \rightarrow Q_1$ .

Implications of the Homomorphism Theorem

The proof has highlighted another useful fact.

The following two are equivalent:

- Finding a homomorphism from  $Q_2$  to  $Q_1$
- Finding a query result for  $Q_2$  over  $\mathcal{I}_1$

 $\rightarrow$  all complexity results for CQ query answering apply

**Theorem 10.4:** Deciding if  $Q_1 \sqsubseteq Q_2$  is NP-complete.

If  $Q_2$  is a tree query (or of bounded treewidth, or of bounded hypertree width) then deciding if  $Q_1 \sqsubseteq Q_2$  is polynomial (in fact LOGCFL-complete).

Note that even in the NP-complete case the problem size is rather small (only queries, no databases)

### Application: CQ Minimisation

**Definition 10.5:** A conjunctive query *Q* is minimal if:

- for all subqueries Q' of Q (that is, queries Q' that are obtained by dropping one or more atoms from Q),
- we find that  $Q' \neq Q$ .

A minimal CQ is also called a core.

It is useful to minimise CQs to avoid unnecessary joins in query answering.

### CQ Minimisation the Direct Way

A simple idea for minimising Q:

- Consider each atom of Q, one after the other
- Check if the subquery obtained by dropping this atom is contained in *Q*

(Observe that the subquery always contains the original query.)

• If yes, delete the atom; continue with the next atom

### CQ Minimisation the Direct Way

A simple idea for minimising Q:

- Consider each atom of Q, one after the other
- Check if the subquery obtained by dropping this atom is contained in *Q*

(Observe that the subquery always contains the original query.)

• If yes, delete the atom; continue with the next atom

**Example 10.6:** Example query Q[v, w]:

 $\exists x, y, z. R(a, y) \land R(x, y) \land S(y, y) \land S(y, z) \land S(z, y) \land T(y, v) \land T(y, w)$ 

ightarrow Simpler notation: write as set and mark answer variables

 $\{R(a,y),R(x,y),S(y,y),S(y,z),S(z,y),T(y,\bar{v}),T(y,\bar{w})\}$ 

Markus Krötzsch, 10th May 2022

 $\{R(a,y),R(x,y),S(y,y),S(y,z),S(z,y),T(y,\bar{v}),T(y,\bar{w})\}$ 

Can we map the left side homomorphically to the right side?

R(a, y)	R(a, y)	Keep (cannot map constant a)
R(x, y)	R(x, y)	Drop; map $R(x, y)$ to $R(a, y)$
S(y, y)	S(y, y)	Keep (no other atom of form $S(t, t)$ )
S(y,z)	S(y,z)	Drop; map $S(y, z)$ to $S(y, y)$
S(z, y)	S(z, y)	Drop; map $S(z, y)$ to $S(y, y)$
$T(y, \bar{v})$	$T(y, \bar{v})$	Keep (cannot map answer variable)
$T(y, \bar{w})$	$T(y, \bar{w})$	Keep (cannot map answer variable)

Core:  $\exists y. R(a, y) \land S(y, y) \land T(y, v) \land T(y, w)$ 

### CQ Minimisation

#### Does this algorithm work?

• Is the result minimal?

Or could it be that some atom that was kept can be dropped later, after some other atoms were dropped?

• Is the result unique?

Or does the order in which we consider the atoms matter?

### CQ Minimisation

#### Does this algorithm work?

• Is the result minimal?

Or could it be that some atom that was kept can be dropped later, after some other atoms were dropped?

• Is the result unique?

Or does the order in which we consider the atoms matter?

**Theorem 10.7:** The CQ minimisation algorithm always produces a core, and this result is unique up to query isomorphisms (bijective renaming of non-result variables).

Proof: exercise

Even when considering single atoms, the homomorphism question is NP-hard:

**Theorem 10.8:** Given a conjunctive query Q with an atom A, it is NP-complete to decide if there is a homomorphism from Q to  $Q \setminus \{A\}$ .

#### Even when considering single atoms, the homomorphism question is NP-hard:

**Theorem 10.8:** Given a conjunctive query Q with an atom A, it is NP-complete to decide if there is a homomorphism from Q to  $Q \setminus \{A\}$ .

#### Proof: We reduce 3-colourability of connected graphs to this special kind of

homomorphism problem. (If a graph consists of several connected components, then 3-colourability can be solved independently for each, hence 3-colourability is NP-hard when considering only connected graphs.)

#### Even when considering single atoms, the homomorphism question is NP-hard:

- Then there is a homomorphism  $\mu$  from G to the colouring template
- We can extend  $\mu$  to the colouring template (mapping each colour to itself)
- Then  $\mu$  is a homomorphism  $Q \rightarrow Q \setminus \{A\}$
- ( $\Leftarrow$ ) If there is a homomorphism  $Q \rightarrow Q \setminus \{A\}$  then *G* is 3-colourable.
  - Let  $\mu$  be such a homomorphism, and let A = R(f, e).

Even when considering single atoms, the homomorphism question is NP-hard:

**Theorem 10.8:** Given a conjunctive query Q with an atom A, it is NP-complete to decide if there is a homomorphism from Q to  $Q \setminus \{A\}$ .

**Proof (continued):** ( $\Rightarrow$ ) If *G* is 3-colourable then there is a homomorphism  $Q \rightarrow Q \setminus \{A\}$ .

- Then there is a homomorphism  $\mu$  from G to the colouring template
- We can extend  $\mu$  to the colouring template (mapping each colour to itself)
- Then  $\mu$  is a homomorphism  $Q \rightarrow Q \setminus \{A\}$

- Let  $\mu$  be such a homomorphism, and let A = R(f, e).
- Since  $Q \setminus \{A\}$  contains the pattern R(s, t), R(t, s) only in the colouring template,  $\mu(e) \in \{r, g, b\}$  and  $\mu(f) \in \{r, g, b\}$ .

Even when considering single atoms, the homomorphism question is NP-hard:

**Theorem 10.8:** Given a conjunctive query Q with an atom A, it is NP-complete to decide if there is a homomorphism from Q to  $Q \setminus \{A\}$ .

**Proof (continued):** ( $\Rightarrow$ ) If *G* is 3-colourable then there is a homomorphism  $Q \rightarrow Q \setminus \{A\}$ .

- Then there is a homomorphism  $\mu$  from G to the colouring template
- We can extend  $\mu$  to the colouring template (mapping each colour to itself)
- Then  $\mu$  is a homomorphism  $Q \rightarrow Q \setminus \{A\}$

- Let  $\mu$  be such a homomorphism, and let A = R(f, e).
- Since  $Q \setminus \{A\}$  contains the pattern R(s, t), R(t, s) only in the colouring template,  $\mu(e) \in \{r, g, b\}$  and  $\mu(f) \in \{r, g, b\}$ .
- Since the colouring template is not connected to other atoms of *Q*, μ must therefore map all elements of *Q* to the colouring template.

Even when considering single atoms, the homomorphism question is NP-hard:

**Theorem 10.8:** Given a conjunctive query Q with an atom A, it is NP-complete to decide if there is a homomorphism from Q to  $Q \setminus \{A\}$ .

**Proof (continued):** ( $\Rightarrow$ ) If *G* is 3-colourable then there is a homomorphism  $Q \rightarrow Q \setminus \{A\}$ .

- Then there is a homomorphism  $\mu$  from G to the colouring template
- We can extend  $\mu$  to the colouring template (mapping each colour to itself)
- Then  $\mu$  is a homomorphism  $Q \rightarrow Q \setminus \{A\}$

- Let  $\mu$  be such a homomorphism, and let A = R(f, e).
- Since  $Q \setminus \{A\}$  contains the pattern R(s, t), R(t, s) only in the colouring template,  $\mu(e) \in \{r, g, b\}$  and  $\mu(f) \in \{r, g, b\}$ .
- Since the colouring template is not connected to other atoms of *Q*, μ must therefore map all elements of *Q* to the colouring template.
- Hence,  $\mu$  induces a 3-colouring.

# CQ Minimisation: Complexity

Even when considering single atoms, the homomorphism question is NP-hard:

**Theorem 10.8:** Given a conjunctive query Q with an atom A, it is NP-complete to decide if there is a homomorphism from Q to  $Q \setminus \{A\}$ .

**Proof (summary):** For an arbitrary connected graph G, we constructed a query Q with atom A, such that

- *G* is 3-colourable if and only if
- there is a homomorphism  $Q \rightarrow Q \setminus \{A\}$ .

Since the former problem is NP-hard, so is the latter.

Inclusion in NP is obvious (just guess the homomorphism).

# CQ Minimisation: Complexity

Even when considering single atoms, the homomorphism question is NP-hard:

**Theorem 10.8:** Given a conjunctive query Q with an atom A, it is NP-complete to decide if there is a homomorphism from Q to  $Q \setminus \{A\}$ .

**Proof (summary):** For an arbitrary connected graph G, we constructed a query Q with atom A, such that

- G is 3-colourable if and only if
- there is a homomorphism  $Q \rightarrow Q \setminus \{A\}$ .

Since the former problem is NP-hard, so is the latter. Inclusion in NP is obvious (just guess the homomorphism).

Checking minimality is the dual problem, hence:

**Theorem 10.9:** Deciding if a conjunctive query Q is minimal (that is: a core) is coNP-complete.

#### However, the size of queries is usually small enough for minimisation to be feasible.

Markus Krötzsch, 10th May 2022

Database Theory

# Summary and Outlook

Perfect query optimisation is possible for conjunctive queries  $\sim$  Homomorphism problem, similar to query answering  $\sim$  NP-complete

Using this, conjunctive queries can effectively be minimised
