Review: Space Complexity Classes

Recall our earlier definitions of space complexities:

```
Definition 9.1: Let f: \mathbb{N} \to \mathbb{R}^+ be a function.
```

- (1) $\mathsf{DSpace}(f(n))$ is the class of all languages L for which there is an O(f(n))-space bounded Turing machine deciding L .
- (2) $\operatorname{NSpace}(f(n))$ is the class of all languages $\mathbf L$ for which there is an O(f(n))-space bounded nondeterministic Turing machine deciding $\mathbf L$.

Being O(f(n))-space bounded requires a (nondeterministic) TM

- to halt on every input and
- to use $\leq f(|w|)$ tape cells on every computation path.

Space Complexity Classes

Some important space complexity classes:

$$\mathsf{L} = \mathsf{LogSpace} = \mathsf{DSpace}(\log n) \qquad \qquad \mathsf{logarithmic space}$$

$$\mathsf{PSpace} = \bigcup_{d \geq 1} \mathsf{DSpace}(n^d) \qquad \qquad \mathsf{polynomial space}$$

$$\mathsf{ExpSpace} = \bigcup_{d \geq 1} \mathsf{DSpace}(2^{n^d}) \qquad \qquad \mathsf{exponential space}$$

$$\mathsf{NL} = \mathsf{NLogSpace} = \mathsf{NSpace}(\log n) \qquad \qquad \mathsf{nondet. logarithmic space}$$

$$\mathsf{NPSpace} = \bigcup_{d \geq 1} \mathsf{NSpace}(n^d) \qquad \qquad \mathsf{nondet. polynomial space}$$

$$\mathsf{NExpSpace} = \bigcup_{d \geq 1} \mathsf{NSpace}(2^{n^d}) \qquad \qquad \mathsf{nondet. exponential space}$$

The Power of Space

Space seems to be more powerful than time because space can be reused.

Example 9.2: Sat can be solved in linear space:

Just iterate over all possible truth assignments (each linear in size) and check if one satisfies the formula.

Example 9.3: Tautology can be solved in linear space:

Just iterate over all possible truth assignments (each linear in size) and check if all satisfy the formula.

More generally: $NP \subseteq PSpace$ and $coNP \subseteq PSpace$

Linear Compression

Theorem 9.4: For every function $f: \mathbb{N} \to \mathbb{R}^+$, for all $c \in \mathbb{N}$, and for every f-space bounded (deterministic/nondeterministic) Turing machine \mathcal{M} :

there is a $\max\{1, \frac{1}{c}f(n)\}$ -space bounded (deterministic/nondeterministic) Turing machine \mathcal{M}' that accepts the same language as \mathcal{M} .

Proof idea: Similar to (but much simpler than) linear speed-up.

This justifies using *O*-notation for defining space classes.

Markus Krötzsch, 15th Nov 2021

Tape Reduction

Theorem 9.5: For every function $f : \mathbb{N} \to \mathbb{R}^+$ all $k \ge 1$ and $\mathbf{L} \subseteq \Sigma^*$:

If **L** can be decided by an f-space bounded k-tape Turing-machine, then it can also be decided by an f-space bounded 1-tape Turing-machine.

Proof idea: Combine tapes with a similar reduction as for time. Compress space to avoid linear increase.

Note: We still use a separate read-only input tape to define some space complexities, such as LogSpace.

Time vs. Space

```
Theorem 9.6: For all functions f: \mathbb{N} \to \mathbb{R}^+: \mathsf{DTime}(f) \subseteq \mathsf{DSpace}(f) \qquad \mathsf{and} \qquad \mathsf{NTime}(f) \subseteq \mathsf{NSpace}(f)
```

Proof: Visiting a cell takes at least one time step.

```
Theorem 9.7: For all functions f: \mathbb{N} \to \mathbb{R}^+ with f(n) \ge \log n: \mathsf{DSpace}(f) \subseteq \mathsf{DTime}(2^{O(f)}) \qquad \mathsf{and} \qquad \mathsf{NSpace}(f) \subseteq \mathsf{DTime}(2^{O(f)})
```

Proof: Based on configuration graphs and a bound on the number of possible configurations. **Proof:** Build the configuration graph (time $2^{O(f(n))}$) and find a path from the start to an accepting stop configuration (time $2^{O(f(n))}$).

Number of Possible Configurations

Let $\mathcal{M}:=(Q,\Sigma,\Gamma,q_0,\delta,q_{\text{start}})$ be a 2-tape Turing machine (1 read-only input tape + 1 work tape)

Recall: A configuration of \mathcal{M} is a quadruple (q, p_1, p_2, x) where

- $q \in Q$ is the current state,
- $p_i \in \mathbb{N}$ is the head position on tape i, and
- $x \in \Gamma^*$ is the tape content.

Let $w \in \Sigma^*$ be an input to \mathcal{M} and n := |w|.

- Then also $p_1 \le n$.
- If \mathcal{M} is f(n)-space bounded we can assume $p_2 \le f(n)$ and $|x| \le f(n)$

Hence, there are at most

$$|O| \cdot n \cdot f(n) \cdot |\Gamma|^{f(n)} = n \cdot 2^{O(f(n))} = 2^{O(f(n))}$$

different configurations on inputs of length n (the last equality requires $f(n) \ge \log n$).

Markus Krötzsch, 15th Nov 2021

Configuration Graphs

The possible computations of a TM \mathcal{M} (on input w) form a directed graph:

- Vertices: configurations that M can reach (on input w)
- Edges: there is an edge from C₁ to C₂ if C₁ ⊢M C₂
 (C₂ reachable from C₁ in a single step)

This yields the configuration graph:

- · Could be infinite in general.
- For f(n)-space bounded 2-tape TMs, there can be at most $2^{O(f(n))}$ vertices and $(2^{O(f(n))})^2 = 2^{O(f(n))}$ edges

A computation of \mathcal{M} on input w corresponds to a path in the configuration graph from the start configuration to a stop configuration.

Hence, to test if \mathcal{M} accepts input w,

- construct the configuration graph and
- find a path from the start to an accepting stop configuration.

Time vs. Space

```
Theorem 9.6: For all functions f: \mathbb{N} \to \mathbb{R}^+: \mathsf{DTime}(f) \subseteq \mathsf{DSpace}(f) \qquad \mathsf{and} \qquad \mathsf{NTime}(f) \subseteq \mathsf{NSpace}(f)
```

Proof: Visiting a cell takes at least one time step.

```
Theorem 9.7: For all functions f: \mathbb{N} \to \mathbb{R}^+ with f(n) \ge \log n: \mathsf{DSpace}(f) \subseteq \mathsf{DTime}(2^{O(f)}) \qquad \mathsf{and} \qquad \mathsf{NSpace}(f) \subseteq \mathsf{DTime}(2^{O(f)})
```

Proof: Based on configuration graphs and a bound on the number of possible configurations. **Proof:** Build the configuration graph (time $2^{O(f(n))}$) and find a path from the start to an accepting stop configuration (time $2^{O(f(n))}$).

Basic Space/Time Relationships

Applying the results of the previous slides, we get the following relations:

$$L \subseteq NL \subseteq P \subseteq NP \subseteq PSpace \subseteq NPSpace \subseteq ExpTime \subseteq NExpTime$$

We also noted $P \subseteq coNP \subseteq PSpace$.

Open questions:

- What is the relationship between space classes and their co-classes?
- What is the relationship between deterministic and non-deterministic space classes?

Nondeterminism in Space

Most experts think that nondeterministic TMs can solve strictly more problems when given the same amount of time than a deterministic TM:

Most believe that $P \subseteq NP$

How about nondeterminism in space-bounded TMs?

Theorem 9.8 (Savitch's Theorem, 1970): For any

function $f : \mathbb{N} \to \mathbb{R}^+$ with $f(n) \ge \log n$:

 $NSpace(f(n)) \subseteq DSpace(f^2(n)).$

That is: nondeterminism adds almost no power to space-bounded TMs!

Markus Krötzsch, 15th Nov 2021 Complexity Theory slide 13 of 21

Consequences of Savitch's Theorem

Theorem 9.8 (Savitch's Theorem, 1970): For any function $f: \mathbb{N} \to \mathbb{R}^+$ with $f(n) \ge \log n$:

$$NSpace(f(n)) \subseteq DSpace(f^2(n)).$$

П

Corollary 9.9: PSpace = NPSpace.

Proof: PSpace \subseteq NPSpace is clear. The converse follows since the square of a polynomial is still a polynomial.

Similarly for "bigger" classes, e.g., ExpSpace = NExpSpace.

Corollary 9.10: $NL \subseteq DSpace(O(\log^2 n)).$

Note that $\log^2(n) \notin O(\log n)$, so we do not obtain NL = L from this.

Markus Krötzsch, 15th Nov 2021 Complexity Theory slide 14 of 21

Proving Savitch's Theorem

Simulating nondeterminism with more space:

- Use configuration graph of nondeterministic space-bounded TM
- · Check if an accepting configuration can be reached
- Store only one computation path at a time (depth-first search)

This still requires exponential space. We want quadratic space!

What to do?

Things we can do:

- Store one configuration:
 - one configuration requires $\log n + O(f(n))$ space
 - if f(n) ≥ log n, then this is O(f(n)) space
- Store f(n) configurations (remember we have $f^2(n)$ space)
- Iterate over all configurations (one by one)

Proving Savitch's Theorem: Key Idea

To find out if we can reach an accepting configuration, we solve a slightly more general question:

YIELDABILITY

Input: TM configurations C_1 and C_2 , integer k

Problem: Can TM get from C_1 to C_2 in at most k steps?

Approach: check if there is an intermediate configuration C' such that

- (1) C_1 can reach C' in k/2 steps and
- (2) C' can reach C_2 in k/2 steps
- \rightarrow Deterministic: we can try all C' (iteration)
- → Space-efficient: we can reuse the same space for both steps

An Algorithm for Yieldability

```
01 CANYIELD(C_1, C_2, k) {
     if k = 1:
02
03
       return (C_1 = C_2) or (C_1 \vdash_M C_2)
     else if k > 1:
04
05
       for each configuration C of \mathcal{M} for input size n:
06
          if CanYield (C_1, C, k/2) and
             CANYIELD (C, C_2, k/2):
07
80
            return true
09
    // eventually, if no success:
10
     return false
11 }
```

• We only call CanYield only with k a power of 2, so $k/2 \in \mathbb{N}$

Space Requirement for the Algorithm

```
01 CANYIELD(C_1, C_2, k) {
     if k = 1:
02
    return (C_1 = C_2) or (C_1 \vdash_M C_2)
     else if k > 1:
04
05
       for each configuration C of \mathcal{M} for input size n:
         if CanYield(C_1, C, k/2) and
06
             CANYIELD(C, C_2, k/2):
07
08
            return true
     // eventually, if no success:
09
10
     return false
11 }
```

- During iteration (line 05), we store one C in O(f(n))
- Calls in lines 06 and 07 can reuse the same space
- Maximum depth of recursive call stack: log₂ k

Overall space usage: $O(f(n) \cdot \log k)$

Simulating Nondeterministic Space-Bounded TMs

Input: TM \mathcal{M} that runs in NSpace(f(n)); input word w of length n

Algorithm:

- Modify M to have a unique accepting configuration C_{accept}: when accepting, erase tape and move head to the very left
- Select d such that $2^{df(n)} \ge |Q| \cdot n \cdot f(n) \cdot |\Gamma|^{f(n)}$
- Return CanYield(C_{start} , C_{accept} ,k) with $k = 2^{df(n)}$

Space requirements:

CanYield runs in space

$$O(f(n) \cdot \log k) = O(f(n) \cdot \log 2^{df(n)}) = O(f(n) \cdot df(n)) = O(f^{2}(n))$$

Did We Really Do It?

"Select d such that $2^{df(n)} \ge |Q| \cdot n \cdot f(n) \cdot |\Gamma|^{f(n)}$ "

How does the algorithm actually do this?

- f(n) was not part of the input!
- Even if we knew f, it might not be easy to compute!

Solution: replace f(n) by a parameter ℓ and probe its value

- (1) Start with $\ell = 1$
- (2) Check if \mathcal{M} can reach any configuration with more than ℓ tape cells (iterate over all configurations of size $\ell + 1$; use CanYield on each)
- (3) If yes, increase ℓ by 1; goto (2)
- (4) Run algorithm as before, with f(n) replaced by ℓ

Therefore: we don't need to know f at all. This finishes the proof.

П

Summary: Relationships of Space and Time

Summing up, we get the following relations:

$$L \subseteq NL \subseteq P \subseteq NP \subseteq PSpace = NPSpace \subseteq ExpTime \subseteq NExpTime$$

We also noted $P \subseteq coNP \subseteq PSpace$.

Open questions:

- Is Savitch's Theorem tight?
- Are there any interesting problems in these space classes?
- We have PSpace = NPSpace = coNPSpace.
 But what about L, NL, and coNL?

→ the first: nobody knows (YCTBF); the others: see upcoming lectures
