A New n-ary Existential Quantifier in Description Logics

[1] Theoretical Computer Science, TU Dresden, Germany
[2] Process Systems Engineering, RWTH Aachen, Germany

Abstract. Motivated by a chemical process engineering application, we introduce a new concept constructor in Description Logics (DLs), an n-ary variant of the existential restriction constructor, which generalizes both the usual existential restrictions and so-called qualified number restrictions. We show that the new constructor can be expressed in $\mathcal{ALCQ}$, the extension of the basic DL $\mathcal{ALC}$ by qualified number restrictions. However, this representation results in an exponential blow-up. By giving direct algorithms for $\mathcal{ALC}$ extended with the new constructor, we can show that the complexity of reasoning in this new DL is actually not harder than the one of reasoning in $\mathcal{ALCQ}$. Moreover, in our chemical process engineering application, a restricted DL that provides only the new constructor together with conjunction, and satisfies an additional restriction on the occurrence of roles names, is sufficient. For this DL, the subsumption problem is polynomial.

1 Introduction

Description Logics (DLs) [2] are a class of knowledge representation formalisms in the tradition of semantic networks and frames, which can be used to represent the terminological knowledge of an application domain in a structured and formally well-understood way. DL systems provide their users with inference services (like computing the subsumption hierarchy) that deduce implicit knowledge from the explicitly represented knowledge. For these inference services to be feasible, the underlying inference problems must at least be decidable, and preferably of low complexity. This is only possible if the expressiveness of the DL employed by the system is restricted in an appropriate way. Because of this restriction of the expressive power of DLs, various application-driven language extensions have been proposed in the literature (see, e.g., [3, 9, 22, 16]), some of which have been integrated into state-of-the-art DL systems [15, 13].

The present paper considers a new concept constructor that is motivated by a process engineering application [23]. This constructor is an n-ary variant of the usual existential restriction operator available in most DLs. To motivate the need for this new constructor, assume that we want to describe a chemical plant that has a reactor with a main reaction, and *in addition* a reactor with a main and a side reaction. Also assume that the concepts *Reactor_with_main_reaction* and *Reactor_with_main_and_side_reaction* are defined such that the first concept

subsumes the second one. We could try to model this chemical plant with the help of the usual existential restriction operator as

$$\begin{aligned} \mathit{Plant} \sqcap \exists \mathit{has\_part}.\mathit{Reactor\_with\_main\_reaction} \sqcap \\ \exists \mathit{has\_part}.\mathit{Reactor\_with\_main\_and\_side\_reaction}. \end{aligned}$$

However, because of the subsumption relationship between the two reactor concepts, this concept is equivalent to

$$\mathit{Plant} \sqcap \exists \mathit{has\_part}.\mathit{Reactor\_with\_main\_and\_side\_reaction},$$

and thus does *not* capture the intended meaning of a plant having *two* reactors, one with a main reaction and the other with a main and a side reaction. To overcome this problem, we consider a new concept constructor of the form $\exists r.(C_1, \ldots, C_n)$, with the intended meaning that it describes all individuals having n *different* r-successors $d_1, \ldots, d_n$ such that d_i belongs to C_i $(i = 1, \ldots, n)$. Given this constructor, our concept can correctly be described as

$$\begin{aligned} \mathit{Plant} \sqcap \exists \mathit{has\_part}.(&\mathit{Reactor\_with\_main\_reaction}, \\ &\mathit{Reactor\_with\_main\_and\_side\_reaction}). \end{aligned}$$

The situation differs from other application-driven language extensions in that the new constructor can actually be expressed using constructors available in the DL $\mathcal{ALCQ}$, which can be handled by state-of-the-art DL systems (Section 3). Thus, the new constructor can be seen as syntactic sugar; nevertheless, it makes sense to introduce it explicitly since this speeds up reasoning. In fact, expressing the new constructor with the ones available in $\mathcal{ALCQ}$ results in an exponential blow-up. In addition, the translation introduces many "expensive" constructors (disjunction and qualified number restrictions). For this reason, even highly optimized DL systems like RACER [13] cannot handle the translated concepts in a satisfactory way. In contrast, the direct introduction of the new constructor into $\mathcal{ALC}$ does not increase the complexity of reasoning (Section 4). Moreover, in the process engineering application [23] mentioned above, the rather inexpressive DL $\mathcal{EL}^{(n)}$ that provides only the new constructor together with conjunction is sufficient. In addition, only concept descriptions are used where in each conjunction there is at most one n-ary existential restriction for each role. For this restricted DL, the subsumption problem is polynomial (Section 5). If this last restriction is removed, then subsumption is in coNP, but the exact complexity of the subsumption problem in $\mathcal{EL}^{(n)}$ is still open (Section 6). Because of space constraints, some of the technical details are omitted: they can be found in [5].

2 The DL $\mathcal{ALCQ}$

Concept descriptions are inductively defined with the help of a set of *constructors*, starting with a set N_C of *concept names* and a set N_R of *role names*. The

Name	Syntax	Semantics
conjunction	$C \sqcap D$	$C^{\mathcal{I}} \cap D^{\mathcal{I}}$
negation	$\neg C$	$\Delta^{\mathcal{I}} \setminus C^{\mathcal{I}}$
at-least qualified number restriction	$\geqslant n\, r.C$	$\{x \mid \mathit{card}(\{y \mid \ (x,y) \in r^{\mathcal{I}} \ \wedge y \in C^{\mathcal{I}}\}) \geq n\}$

Table 1. Syntax and semantics of $\mathcal{ALCQ}$.

constructors determine the expressive power of the DL. In this section, we restrict the attention to the DL $\mathcal{ALCQ}$, whose concept descriptions are formed using the constructors shown in Table 1. Using these constructors, several other constructors can be defined as abbreviations:

- $C \sqcup D := \neg(\neg C \sqcap \neg D)$ (disjunction),
- $\top := A \sqcup \neg A$ for a concept name A (top-concept),
- $\exists r.C := \geqslant 1\, r.C$ (existential restriction),
- $\forall r.C := \neg\exists r.\neg C$ (value restriction),
- $\leqslant n\, r.C := \neg(\geqslant (n+1)\, r.C)$ (at-most restriction).

The semantics of $\mathcal{ALCQ}$-concept descriptions is defined in terms of an *interpretation* $\mathcal{I} = (\Delta^{\mathcal{I}}, \cdot^{\mathcal{I}})$. The domain $\Delta^{\mathcal{I}}$ of $\mathcal{I}$ is a non-empty set of individuals and the interpretation function $\cdot^{\mathcal{I}}$ maps each concept name $A \in N_C$ to a subset $A^{\mathcal{I}}$ of $\Delta^{\mathcal{I}}$ and each role $r \in N_R$ to a binary relation $r^{\mathcal{I}}$ on $\Delta^{\mathcal{I}}$. The extension of $\cdot^{\mathcal{I}}$ to arbitrary concept descriptions is inductively defined, as shown in the third column of Table 1. Here, the function *card* yields the cardinality of the given set.

A *general $\mathcal{ALCQ}$-TBox* is a finite set of general concept inclusions (GCIs) $C \sqsubseteq D$ where C, D are $\mathcal{ALCQ}$-concept descriptions. The interpretation $\mathcal{I}$ is a model of the general $\mathcal{ALCQ}$-TBox $\mathcal{T}$ iff it satisfies all its GCIs, i.e., if $C^{\mathcal{I}} \subseteq D^{\mathcal{I}}$ holds for all GCIs $C \sqsubseteq D$ in $\mathcal{T}$.

We use $C \equiv D$ as an abbreviation of the two GCIs $C \sqsubseteq D$, $D \sqsubseteq C$. An *acyclic $\mathcal{ALCQ}$-TBox* is a finite set of *concept definitions* of the form $A \equiv C$ (where A is a concept name and C an $\mathcal{ALCQ}$-concept description) that does not contain multiple definitions or cyclic dependencies between the definitions. Concept names occurring on the left-hand side of a concept definition are called *defined* whereas the others are called *primitive*.

Given two $\mathcal{ALCQ}$-concept descriptions C, D we say that C *is subsumed by* D *w.r.t. the general TBox* $\mathcal{T}$ ($C \sqsubseteq_{\mathcal{T}} D$) iff $C^{\mathcal{I}} \subseteq D^{\mathcal{I}}$ for all models $\mathcal{I}$ of $\mathcal{T}$. Subsumption w.r.t. an acyclic TBox and subsumption between concept descriptions (where $\mathcal{T}$ is empty) are special cases of this definition. In the latter case we write $C \sqsubseteq D$ in place of $C \sqsubseteq_{\emptyset} D$. The concept description C is *satisfiable* (w.r.t. the general TBox $\mathcal{T}$) iff there is an interpretation $\mathcal{I}$ (a model $\mathcal{I}$ of $\mathcal{T}$) such that $C^{\mathcal{I}} \neq \emptyset$.

The complexity of the subsumption problem in $\mathcal{ALCQ}$ depends on the presence of GCIs. Subsumption of $\mathcal{ALCQ}$-concept descriptions (with or without acyclic TBoxes) is PSPACE-complete and subsumption w.r.t. a general $\mathcal{ALCQ}$-

TBox is ExpTime-complete [24].[1] These results hold both for unary and binary coding of the numbers in number restrictions, but in this paper we restrict the attention to unary coding (where the size of the number n is counted as n rather than $\log n$).

3 The new constructor

The general syntax of the new constructor is

$$\exists r.(C_1, \ldots, C_n)$$

where $r \in N_R$, $n \geq 1$, and $C_1, \ldots, C_n$ are concept descriptions. We call this expression an *n-ary existential restriction*. Its semantics is defined as

$$\exists r.(C_1, \ldots, C_n)^{\mathcal{I}} := \{x \mid \exists y_1, \ldots, y_n.\ (x, y_1) \in r^{\mathcal{I}} \wedge \ldots \wedge (x, y_n) \in r^{\mathcal{I}} \wedge y_1 \in C_1^{\mathcal{I}} \wedge \ldots \wedge y_n \in C_n^{\mathcal{I}} \wedge \textstyle\bigwedge_{1 \leq i < j \leq n} y_i \neq y_j\}.$$

We call the DL whose concept descriptions are formed using the constructors conjunction, negation, and n-ary existential restriction $\mathcal{EL}^{(n)}\mathcal{C}$. It is an immediate consequence of the semantics of n-ary existential restrictions that the at-least restriction $\geqslant n\, r.C$ can be expressed by the n-ary existential restriction $\exists r.(C, \ldots, C)$.[2] Consequently, all of $\mathcal{ALCQ}$ can be expressed within $\mathcal{EL}^{(n)}\mathcal{C}$.

Conversely, can we express n-ary existential restrictions within $\mathcal{ALCQ}$? We have seen in the introduction that, in general, $\exists r.(C_1, \ldots, C_n)$ cannot be replaced by the conjunction $\exists r.C_1 \sqcap \ldots \sqcap \exists r.C_n$ since this conjunction does not ensure the existence of n *different* r-successors. However, $\mathcal{ALCQ}$ provides us with the more expressive qualified number restriction constructor. Let us first consider the case $n = 2$. We claim that $\exists r.(C_1, C_2)$ can be expressed by the $\mathcal{ALCQ}$-concept description

$$D := (\geqslant 1\, r.C_1) \sqcap (\geqslant 1\, r.C_2) \sqcap (\geqslant 2\, r.(C_1 \sqcup C_2)).$$

It is clear that any individual belonging to $\exists r.(C_1, C_2)$ also belongs to D. Conversely, assume that x belongs to D. Then x has two distinct r-successors y_1, y_2, both belonging to $C_1 \sqcup C_2$. If one of them belongs to C_1 and the other to C_2, then we are done. Otherwise, we have two cases: (i) both belong to $C_1 \sqcap \neg C_2$, or (ii) both belong to $\neg C_1 \sqcap C_2$. We restrict our attention to the first case (since the second is symmetric). Due to the conjunct $\geqslant 1\, r.C_2$ in D, x has an r-successor in C_2, which is different from y_1 since y_1 does not belong to C_2. Consequently, there are two distinct r-successors of x, one belonging to C_1 and the other belonging to C_2, which shows that x belongs to $\exists r.(C_1, C_2)$.

This result can be extended to arbitrary n.

[1] In [24], acyclic TBoxes are not considered, but it is easy to show that the usual approach for handling acyclic TBoxes without using exponential space [18] extends to $\mathcal{ALCQ}$ (see [6]).

[2] Since we assume unary coding of numbers in number restrictions, this translation is linear. Otherwise, it would be exponential.

Theorem 1. *The n-ary existential restriction constructor can be expressed within $\mathcal{ALCQ}$, and thus $\mathcal{ALCQ}$ and $\mathcal{EL}^{(n)}\mathcal{C}$ have the same expressive power.*

To prove this theorem we show that $\exists r.(C_1, \ldots, C_n)$ can be expressed by the $\mathcal{ALCQ}$-concept description

$$D_n := \bigsqcap_{\{i_1,\ldots,i_k\}\subseteq\{1,\ldots,n\}} (\geqslant k\, r.(C_{i_1} \sqcup \ldots \sqcup C_{i_k})).$$

It is again clear that any individual belonging to the concept $\exists r.(C_1, \ldots, C_n)$ also belongs to D_n. The other direction is an easy consequence of Hall's theorem [14]. Let $F = (S_1, \ldots, S_n)$ be a finite family of sets. This family has a *system of distinct representatives (SDR)* iff there are n distinct elements $s_1, \ldots, s_n$ such that $s_i \in S_i$ $(i = 1, \ldots, n)$.

Theorem 2 (Hall). *The family $F = (S_1, \ldots, S_n)$ has an SDR iff card$(S_{i_1} \cup \ldots \cup S_{i_k}) \geq k$ for all $\{i_1, \ldots, i_k\} \subseteq \{1, \ldots, n\}$, where $i_1, \ldots, i_k$ are distinct.*

Now, assume that the individual x belongs to D_n. For $i = 1, \ldots, n$, let S_i be the set of r-successors of x that belong to C_i. By the definition of D_n, the family $(S_1, \ldots, S_n)$ satisfies the condition of Hall's theorem, and thus it has an SDR. This SDR obviously shows that x belongs to $\exists r.(C_1, \ldots, C_n)$.

The proof of Theorem 1 shows that the subsumption problem in $\mathcal{EL}^{(n)}\mathcal{C}$ can be reduced to the subsumption problem in $\mathcal{ALCQ}$, and thus DL systems like RACER that can handle $\mathcal{ALCQ}$ can in principle be used to compute subsumption in $\mathcal{EL}^{(n)}\mathcal{C}$. However, the translation from $\mathcal{EL}^{(n)}\mathcal{C}$ into $\mathcal{ALCQ}$ described above is obviously exponential. In addition, the constructs it introduces (disjunctions and qualified number restrictions) are hard to handle for tableau-based subsumption algorithms like the one used by RACER. In fact, faced with the $\mathcal{ALCQ}$-translations of the $\mathcal{EL}^{(n)}\mathcal{C}$-concept descriptions

$$C := \exists r.(A_1 \sqcap B_1, A_2 \sqcap B_2, A_3 \sqcap B_3, A_4 \sqcap B_4),$$
$$D := \exists r.(A_1, A_2, A_3, A_4),$$

it takes RACER[3] 57 minutes to find out that $C \sqsubseteq D$. For the 5-ary variant of this example, RACER did not finish its computation within 4 hours.

This problem can be due either to the inherently higher complexity of reasoning in $\mathcal{EL}^{(n)}\mathcal{C}$, or to the translation. We will see in the next section that the latter is the culprit.

4 Complexity of reasoning in $\mathcal{EL}^{(n)}\mathcal{C}$

The exponential translation of $\mathcal{EL}^{(n)}\mathcal{C}$-concepts into $\mathcal{ALCQ}$-concepts together with the known complexity of the subsumption problem in $\mathcal{ALCQ}$ (see Section 2) yields the following complexity upper-bounds for the subsumption problem in $\mathcal{EL}^{(n)}\mathcal{C}$: EXPSPACE for subsumption of concept descriptions and 2EXPTIME for

define procedure $\mathcal{EL}^{(n)}\mathcal{C}$-$\mathsf{World}(\Delta, \Gamma)$
  if Δ is not a type for Γ **then**
    return false
  for all $r \in \mathsf{rol}_\exists(\Delta)$ **do**
    non-deterministically choose an $n \leq N_r(\Gamma)$ and sets $\Psi_0, \ldots, \Psi_{n-1} \subseteq r\text{-}\,\mathsf{cl}(\Delta)$
    if $\Psi_0, \ldots, \Psi_{n-1}$ is not a successor candidate for Δ w.r.t. Γ **then**
      return false
    for all $i < n$ **do**
      if $\mathcal{EL}^{(n)}\mathcal{C}$-$\mathsf{World}(\Psi_i, r\text{-}\,\mathsf{cl}(\Delta)) =$ false **then**
        return false
  return true

Fig. 1. The procedure $\mathcal{EL}^{(n)}\mathcal{C}$-World.

subsumption w.r.t. a general TBox. The next theorem shows that these upper-bounds are not optimal.

Theorem 3. *The subsumption problem in* $\mathcal{EL}^{(n)}\mathcal{C}$ *is* PSPACE*-complete for subsumption between concept descriptions and* EXPTIME*-complete for subsumption w.r.t. a general TBox.*

The hardness results are an immediate consequence of the corresponding hardness results [11] for the subsumption problem in $\mathcal{ALC}$ (which allows for conjunction, negation, and existential restrictions). Since $\mathcal{EL}^{(n)}\mathcal{C}$ is closed under negation, it is enough to prove the upper bounds for the satisfiability problem. To show the PSPACE-upper bound, we adapt the "witness algorithm" (also called **K**-worlds algorithm) commonly used in modal logics to show that satisfiability in the modal logic **K** is in PSPACE (see, e.g., [7]). The EXPTIME-upper bound is proved by an adaptation of Pratt's "elimination of Hintikka sets" approach to show that satisfiability in propositional dynamic logic (PDL) is in EXPTIME (see also [7]). But first, we must introduce some notation.

In the following, we assume that all concept descriptions are built using only the constructors conjunction, negation, and n-ary existential restriction. We use $\mathsf{sub}(C)$ to denote the set of all *subconcepts* of C, $\mathsf{sub}(\mathcal{T})$ to denote $\bigcup_{C \sqsubseteq D \in \mathcal{T}}(\mathsf{sub}(C) \cup \mathsf{sub}(D))$, and define the *closure* of C and $\mathcal{T}$ as

$$\mathsf{cl}(C, \mathcal{T}) := \mathsf{sub}(C) \cup \mathsf{sub}(\mathcal{T}) \cup \{\neg D \mid D \in \mathsf{sub}(C) \cup \mathsf{sub}(\mathcal{T})\}.$$

We use $\mathsf{cl}(C)$ as an abbreviation for $\mathsf{cl}(C, \emptyset)$. Let Γ be a set of concept descriptions. A set $\Psi \subseteq \Gamma$ is a *type for* Γ iff it satisfies the following conditions:

- for all $C \sqcap D \in \Gamma$: $C \sqcap D \in \Psi$ iff $\{C, D\} \subseteq \Psi$;
- for all $\neg(C \sqcap D) \in \Gamma$: $\neg(C \sqcap D) \in \Psi$ iff $\{\neg C, \neg D\} \cap \Psi \neq \emptyset$;
- for all $\neg C \in \Gamma$: $\neg C \in \Psi$ iff $C \notin \Psi$.

[3] RACER Version 1.7.23; on a Pentium 4 machine, 2 Ghz, 2 GB memory; under Redhat Linux.

define procedure $\mathcal{EL}^{(n)}\mathcal{C}$-Elim$(C, \mathcal{T})$

Set $i := 0$ and $\mathfrak{T}_0$ to the set of all types for C and $\mathcal{T}$

repeat

$\mathfrak{T}_{i+1} := \{\Gamma \in \mathfrak{T}_i \mid \Gamma \text{ is not moribund in } \mathfrak{T}_i\}$

$i := i + 1$

until $\mathfrak{T}_i = \mathfrak{T}_{i-1}$

if there is a $\Gamma \in \mathfrak{T}_i$ with $C \in \Gamma$ **then**

return true

return false

Fig. 2. The procedure $\mathcal{EL}^{(n)}\mathcal{C}$-Elim.

Intiuitively, a type for $\mathsf{cl}(C, \mathcal{T})$ can be used to describe to which subconcepts of $C, \mathcal{T}$ an individual of a given interpretation belongs or not. Individuals having identical types behave the same w.r.t. subconcepts of $C, \mathcal{T}$, and thus, in the algorithms, types can be used to represent the relevant properties of individuals. Basically, the ExpTime-upper bound is due to the fact that there are only exponentially many types for $\mathsf{cl}(C, \mathcal{T})$. In case $\mathcal{T}$ is empty, there are still exponentially many types, but the way one goes through them is such that only polynomially many of them need to be held in memory at the same time.

Let Γ be a set of concept descriptions, and r a role name. Then $\mathsf{rol}_\exists(\Gamma)$ denotes the set of role names r such that $\exists r.(C_1, \ldots, C_k) \in \Gamma$ for some sequence of concept descriptions $C_1, \ldots, C_k$; moreover, for every role name r we set

$$r\text{-}\mathsf{con}(\Gamma) := \{C_1, \ldots, C_k \mid \exists r.(C_1, \ldots, C_k) \in \Gamma \text{ or } \neg\exists r.(C_1, \ldots, C_k) \in \Gamma\},$$
$$r\text{-}\mathsf{cl}(\Gamma) := \{D, \neg D \mid D \in \mathsf{sub}(E) \text{ for some } E \in r\text{-}\mathsf{con}(\Gamma)\},$$
$$N_r(\Gamma) := \textstyle\sum_{\exists r.(C_1,\ldots,C_k)\in\Gamma} k.$$

Finally, let $\Psi \subseteq \Gamma$, $\Phi_0, \ldots, \Phi_{n-1}$ a (possibly empty) sequence of subsets of Γ, and r a role name. Then $\Phi_0, \ldots, \Phi_{n-1}$ is a *successor candidate* for Ψ w.r.t. r and Γ if, for all $\exists r.(C_1, \ldots, C_k) \in \Gamma$, we have $\exists r.(C_1, \ldots, C_k) \in \Psi$ iff there are $i_1, \ldots, i_k < n$ such that $C_j \in \Phi_{i_j}$ for $1 \leq j \leq k$ and $i_j \neq i_\ell$ for $1 \leq j < \ell \leq k$.

The following lemma, whose proof can be found in [5], states that the procedure introduced in Fig. 1 decides satisfiability of $\mathcal{EL}^{(n)}\mathcal{C}$-concept descriptions.

Lemma 1. *The $\mathcal{EL}^{(n)}\mathcal{C}$-concept description C is satisfiable iff there exists a set $\Psi \subseteq \mathsf{cl}(C)$ with $C \in \Psi$ such that $\mathcal{EL}^{(n)}\mathcal{C}$-World$(\Psi, \mathsf{cl}(C))$ returns* true.

In [5] it is also shown that $\mathcal{EL}^{(n)}\mathcal{C}$-World is a non-deterministic algorithm that runs in polynomial space. Because of Savitch's theorem, which says that PSpace = NPSpace, this yields the desired PSpace upper-bound.

Let us now turn to the case of satisfiability w.r.t. a general TBox. Let C be a concept and $\mathcal{T}$ a TBox. A set $\Psi \subseteq \mathsf{cl}(C, \mathcal{T})$ is a *type for C and $\mathcal{T}$* if it is a type for $cl(C, \mathcal{T})$ and additionally satisfies the following property: for all $D \sqsubseteq E \in \mathcal{T}$, $D \in \Psi$ implies $E \in \Psi$.

A type Γ is called *moribund* w.r.t. a set of types $\mathfrak{T}$ if there exists a role name r such that there is no sequence $\Phi_0, \ldots, \Phi_{n-1} \in \mathfrak{T}$ with $n \leq N_r(\Gamma)$ that is a successor candidate for Γ w.r.t. r and $\mathsf{cl}(C, \mathcal{T})$.

Lemma 2. *The procedure $\mathcal{EL}^{(n)}\mathcal{C}$-*Elim *introduced in Fig. 2 decides satisfiability of C w.r.t. $\mathcal{T}$ in exponential time.*

5 A tractable sublanguage

In the chemical process engineering application mentioned above [23], the full expressive power of $\mathcal{EL}^{(n)}\mathcal{C}$ is actually not needed. This application is concerned with supporting the construction of mathematical models of process systems by storing building blocks for such models in a class hierarchy. In order to retrieve building blocks, one can then either browse the hierarchy or formulate query classes. In both cases, the existence of efficient algorithms for computing subsumption between class descriptions is an important prerequisite.

The frame-like formalism for describing classes of such building blocks introduced in [23] can be expressed in the *sublanguage $\mathcal{EL}^{(n)}$ of $\mathcal{EL}^{(n)}\mathcal{C}$*, which allows for conjunction, n-ary existential restrictions, and the top concept. Moreover, since in each frame a given slot-name can be used only once, it is sufficient to consider *restricted $\mathcal{EL}^{(n)}$-concept descriptions* where in each conjunction there is at most one n-ary existential restriction for each role: an $\mathcal{EL}^{(n)}$-concept description is *restricted* iff it is of the form

$$A_1 \sqcap \ldots \sqcap A_n \sqcap \exists r_1.(B_{1,1}, \ldots, B_{1,\ell_1}) \sqcap \ldots \sqcap \exists r_m.(B_{m,1}, \ldots, B_{m,\ell_m}),$$

where $A_1, \ldots, A_n$ are concept names, $r_1, \ldots, r_m$ are *distinct* role names, and $B_{1,1}, \ldots, B_{m,\ell_m}$ are restricted $\mathcal{EL}^{(n)}$-concept descriptions.

For example, the $\mathcal{EL}^{(n)}$-concept description $\exists r.(A, \exists r.(B, C)) \sqcap \exists s.(A, A)$ is restricted whereas the description $\exists r.(A, \exists r.(B, C)) \sqcap \exists r.(A, A)$ is not.

As in the case of $\mathcal{EL}$ [4], the fragment of $\mathcal{EL}^{(n)}$ admitting only unary existential restrictions, restricted $\mathcal{EL}^{(n)}$-concept descriptions can be translated into *$\mathcal{EL}^{(n)}$-description trees*, where the nodes are labeled with sets of concept names and the edges are labeled with role names. For example, the restricted $\mathcal{EL}^{(n)}$-concept descriptions

$$A \sqcap \exists r.(A, B \sqcap \exists r.(B, A), \exists r.(A, A \sqcap B)) \quad \text{and} \quad A \sqcap \exists r.(A, B, \exists r.(A, A))$$

yield the description trees depicted in Fig. 3. Given a restricted $\mathcal{EL}^{(n)}$-concept description C, we denote the corresponding description tree by T_C. Formally, this tree is described by a tuple $T_C = (V, E, v_0, \ell)$, where V is the finite set of nodes, $E \subseteq V \times N_R \times V$ is the set of N_R-labeled edges, $v_0 \in V$ is the root, and $\ell : V \longrightarrow 2^{N_C}$ is the node labeling function.

In [4], it was shown that subsumption between $\mathcal{EL}$-concept descriptions corresponds to the existence of a homomorphism between the corresponding description trees. In $\mathcal{EL}^{(n)}$, we must additionally require that the homomorphism is injective.

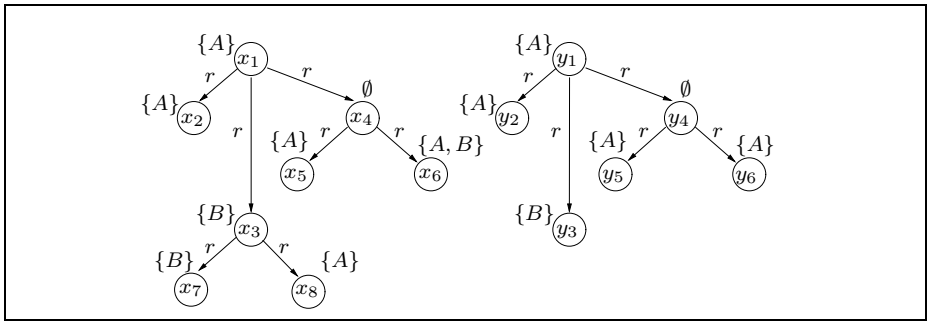

Fig. 3. Two $\mathcal{EL}^{(n)}$-description trees.

Definition 1. *Given two $\mathcal{EL}^{(n)}$-description trees $T_1 = (V_1, E_1, v_{0,1}, \ell_1)$ and $T_2 = (V_2, E_2, v_{0,2}, \ell_2)$, a* homomorphism $\varphi : T_1 \longrightarrow T_2$ *is a mapping $\varphi : V_1 \longrightarrow V_2$ such that*

- $\varphi(v_{0,1}) = v_{0,2}$,
- $\ell_1(v) \subseteq \ell_2(\varphi(v))$ *for all* $v \in V_1$, *and*
- $(\varphi(v), r, \varphi(w)) \in E_2$ *for all* $(v, r, w) \in E_1$.

This homomorphism is an embedding *iff the mapping $\varphi : V_1 \longrightarrow V_2$ is injective.*

For example, mapping y_i to x_i for $i = 1, \ldots, 6$ yields an embedding from the description tree on the right-hand side of Fig. 3 to the description tree on the left-hand side. If we changed the label of x_6 to $\{B\}$, then there would still exist a homomorphism between the two trees (mapping both y_5 and y_6 onto x_5), but not an embedding.

The following theorem can be shown similarly to the proof of the corresponding result for $\mathcal{EL}$ [4] (see [5] for details).

Theorem 4. *Let C, D be restricted $\mathcal{EL}^{(n)}$-concept descriptions and T_C, T_D the corresponding description trees. Then $C \sqsubseteq D$ iff there exists an embedding from T_D into T_C.*

To show that subsumption between restricted $\mathcal{EL}^{(n)}$-concept descriptions is a polynomial-time problem, it remains to be shown that the existence of an embedding can be decided in polynomial time. First, let us recall the well-known bottom-up approach for testing for the existence of a homomorphism [21, 4].

Let $T_1 = (V_1, E_1, v_{0,1}, \ell_1)$ and $T_2 = (V_2, E_2, v_{0,2}, \ell_2)$ be two $\mathcal{EL}^{(n)}$-description trees, and assume that we want to check whether there is a homomorphism from T_1 to T_2. The idea underlying the polynomial time test is to compute, for each $v \in V_1$, the set $\delta(v)$ of all nodes $w \in V_2$ such that there is a homomorphism from the subtree of T_1 with root v to the subtree of T_2 with root w. Once these sets δ are computed for all nodes of T_1, we can simply check whether $v_{0,2}$ belongs to $\delta(v_{0,1})$. The sets $\delta(v)$ are computed in a bottom-up fashion, where a node is treated only after all its successor nodes have been considered:[4]

[4] For example, one can use a postorder tree walk [10] of the nodes of T_1 to realize this.

1. If v is a leaf of T_1, then $\delta(v)$ simply consists of all the nodes $w \in V_2$ such that $\ell_1(v) \subseteq \ell_2(w)$.
2. Let v be a node of T_1 and let $(v, r_1, v_1), \ldots, (v, r_k, v_k)$ be all the edges in E_1 with first component v. Since we work bottom up, we know that the sets $\delta(v_1), \ldots, \delta(v_k)$ have already been computed. The set $\delta(v)$ consists of all the nodes $w \in V_2$ such that
   (a) $\ell_1(v) \subseteq \ell_2(w)$ and
   (b) for each $i, 1 \leq i \leq k$ there exists a node $w_i \in \delta(v_i)$ such that $(w, r_i, w_i) \in E_2$.

It is easy to show that this indeed yields a polynomial-time algorithm for checking the existence of a *homomorphism* between two $\mathcal{EL}^{(n)}$-description trees.

If we want to test for the existence of an *embedding*, we must modify Step 2 of this algorithm. In fact, we must ensure that distinct r-successors of v can be mapped to distinct r-successors of w. This can be achieved as follows:

2′. Let v be a node of T_1, and for each role r let $(v, r, v_{1,r}), \ldots, (v, r, v_{k_r,r})$ be the edges in E_1 with first component v and label r. Since we work bottom up, we know that the sets $\delta(v_{1,r}), \ldots, \delta(v_{k_r,r})$ have already been computed. The set $\delta(v)$ consists of all the nodes $w \in V_2$ satisfying the following two properties:
   (a) $\ell_1(v) \subseteq \ell_2(w)$,
   (b) for all roles r, the family $F_r(w) := (S_{1,r}(w), \ldots, S_{k_r,r}(w))$ has an SDR, where the members of this family are defined as

$$S_{i,r}(w) := \{w' \in \delta(v_{i,r}) \mid (w, r, w') \in E_2\}.$$

Obviously, the existence of an SDR for $F_r(w)$ allows us to map the r-successors of v to *distinct* r-successors of w, and thus construct an embedding. For this algorithm to be polynomial, it remains to be shown that the existence of an SDR can be decided in polynomial time. Note that Hall's characterization of the existence of an SDR obviously does not yield a polynomial-time procedure. However, checking for the existence of an SDR is basically the same as solving the maximum bipartite matching problem, which can be done in polynomial time since it can be reduced to a network flow problem [10].

To be more precise, let $(L \cup R, E)$ be a bipartite graph, i.e., $L \cap R = \emptyset$ and $E \subseteq L \times R$. A *matching* is a subset M of E such that each node in $L \cup R$ occurs at most once in M. This matching is called *maximum* iff there is no other matching having a larger cardinality. As shown in [10], such a maximum matching can be computed in time polynomial in the cardinality of V and E.

Let $F = (S_1, \ldots, S_n)$ be a finite family of finite sets, and let $L := \{1, \ldots, n\}$ and $R = S_1 \cup \ldots \cup S_n$.[5] We define the set of edges of the bipartite graph $G_F = (L \cup R, E)$ as follows:

$$E := \{(i, s) \mid s \in S_i\}.$$

[5] Without loss of generality we can assume that $L \cap R = \emptyset$.

It is easy to see that the family F has an SDR iff the corresponding bipartite graph G_F has a maximum matching of cardinality n. In fact, $(1, s_1), \ldots, (n, s_n)$ is a maximum matching iff $s_1, \ldots, s_n$ is an SDR.

Thus, we have shown that the existence of an embedding can be decided in polynomial time. Together with Theorem 4, this yields the following tractability result:

Corollary 1. *Subsumption between restricted $\mathcal{EL}^{(n)}$-concept descriptions can be decided in polynomial time.*

A first implementation of this polynomial-time algorithm behaves much better than the translation approach on the example concept descriptions C, D from Section 3 and their obvious extensions to larger n. For small n, the subsumption relationship is found immediately (i.e., with no measurable run-time), and even for $n = 100$, the runtime (of our unoptimized implementation) is just 1 second. One could argue that the comparison of these results with the performance of RACER on the $\mathcal{ALCQ}$-translations of C, D and their extensions to larger n is unfair since the culprit is the exponential translation rather than RACER. However, this is the only known translation of $\mathcal{EL}^{(n)}$-concept descriptions into a DL that can be handled by RACER, and it is the one originally used in the process engineering application.

Acyclic TBoxes In the process engineering application, acyclic TBoxes are used to introduce abbreviations for complex concept descriptions. In order to extend the polynomial-time algorithm for subsumption between restricted $\mathcal{EL}^{(n)}$-concept descriptions to subsumption w.r.t. acyclic TBoxes, we must first define what it means that an $\mathcal{EL}^{(n)}$-TBox is restricted. An acyclic $\mathcal{EL}^{(n)}$-TBox is called *restricted* iff its concept definitions are of the form

$$A \equiv P_1 \sqcap \ldots \sqcap P_n \sqcap \exists r_1.(A_{1,1}, \ldots, A_{1,\ell_1}) \sqcap \ldots \sqcap \exists r_m.(A_{m,1}, \ldots, A_{m,\ell_m}),$$

where $A, A_{1,1}, \ldots, A_{m,\ell_m}$ are defined concepts, $P_1, \ldots, P_n$ are primitive concepts, and $r_1, \ldots, r_m$ are *distinct* role names.

Given defined concepts A, B in such a TBox $\mathcal{T}$, we can decide subsumption between A and B w.r.t. $\mathcal{T}$ by first expanding A and B, i.e., replacing defined concept names by their definitions until no more defined concepts occur, and then testing the expanded concept descriptions obtained this way for subsumption. The definition of restricted $\mathcal{EL}^{(n)}$-TBoxes ensures that these expanded concept descriptions are restricted, and thus we can use the subsumption algorithm described above. However, it is well-know that the expansion process may lead to an exponential blow-up, i.e., the expanded concept descriptions can be exponential in the size of the TBox [19].

To overcome this problem, we represent restricted $\mathcal{EL}^{(n)}$-TBoxes as directed acyclic graphs (DAG), and define a notion of embedding that, (i) can be tested in time polynomial in the size of the DAG, and (ii) implies the existence of an embedding between the description trees of the expanded concept descriptions (see [5] for details).

Corollary 2. *Subsumption between defined concepts with respect to restricted acyclic $\mathcal{EL}^{(n)}$-TBoxes can be decided in polynomial time.*

Disjointness statements In the chemical process engineering application motivating this paper, the real-world concepts expressed by primitive concept names are often disjoint. For example, an object cannot be both an apparatus and a plant. Disjointness statements of the form $dis(P, Q)$, where P, Q are primitive concepts, allow us to express such additional knowledge. An interpretation $\mathcal{I}$ is a model of this statement iff $P^{\mathcal{I}} \cap Q^{\mathcal{I}} = \emptyset$.

For restricted $\mathcal{EL}^{(n)}$-concept descriptions, the only effect that disjointness statements have is that they can make concepts unsatisfiable. It is easy to see that the $\mathcal{EL}^{(n)}$-concept description C is unsatisfiable w.r.t. the set of disjointness statements $\mathcal{D}$ iff there is a statement $dis(P, Q)$ in $\mathcal{D}$ and a node v in T_C whose label contains P and Q. Now, assume that C, D are restricted $\mathcal{EL}^{(n)}$-concept descriptions. Then C is subsumed by D w.r.t. $\mathcal{D}$ iff (i) either C is unsatisfiable w.r.t. $\mathcal{D}$, or (ii) both are satisfiable w.r.t. $\mathcal{D}$ and C is subsumed by D without considering $\mathcal{D}$.

Corollary 3. *Subsumption between restricted $\mathcal{EL}^{(n)}$-concept descriptions w.r.t. disjointness statements can be decided in polynomial time.*

6 Unrestricted $\mathcal{EL}^{(n)}$-concept descriptions

In such concept descriptions, several n-ary existential restrictions for the same role r can occur in a conjunction, such as in the description

$$C_u := A \sqcap \exists r.(A, B) \sqcap \exists r.(\exists r.A \sqcap \exists r.A).$$

If we translate this unrestricted $\mathcal{EL}^{(n)}$-concept description into a description tree, then we obtain the tree on the right-hand side of Fig. 3, which is also obtained as a translation of the restricted $\mathcal{EL}^{(n)}$-concept description

$$C_r := A \sqcap \exists r.(A, B, \exists r.(A, A)).$$

To distinguish between these two descriptions, we introduce *distinctness classes*: for each node x in the tree and each role r, the r-successors of x are partitioned into such classes. For example, in the tree corresponding to C_u, the r-successors of y_1 are partitioned into the sets $\{y_2, y_3\}$, $\{y_4\}$, whereas there is only one distinctness class $\{y_2, y_3, y_4\}$ for these nodes in the tree corresponding to C_r.

The notion of an *embedding* that we will use in this section must take these distinctness classes into account. Instead of requiring that the homomorphism φ is injective, we require that for each node x in T_1 and each distinctness class $\{x_1, \ldots, x_k\}$ of r-successors of x, the nodes $\varphi(x_1), \ldots, \varphi(x_k)$ are distinct r-successors of $\varphi(x)$.

However, if we just change the notion of an embedding in this way, then Theorem 4 obviously does not hold for unrestricted $\mathcal{EL}^{(n)}$-concept descriptions.

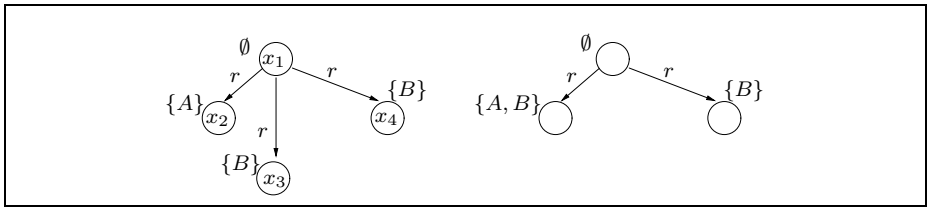

Fig. 4. Identification of $\mathcal{EL}^{(n)}$-description trees.

In fact, if $\varphi(x_1), \ldots, \varphi(x_k)$ do not belong to the same distinctness class, then we cannot be sure that they really represent distinct individuals. For example, if $C = \exists r.A \sqcap \exists r.B$ and $D = \exists r.(A, B)$, then there is an embedding from T_D into T_C, but D does not subsume C.

Thus, an obvious conjecture could be that the embedding must *respect distinctness classes*, i.e., we must require $\varphi(x_1), \ldots, \varphi(x_k)$ to belong to the same distinctness class. However, the following example shows that this requirement is too strong. Let $C = \exists r.A \sqcap \exists r.(B, B)$ and $D = \exists r.(A, B)$. There is no embedding from T_D to T_C that respects distinctness classes, but it is easy to see that D subsumes C.

Before we can formulate a correct characterization of subsumption between unrestricted $\mathcal{EL}^{(n)}$-concept descriptions, we must introduce some notation. Given a description tree $T = (V, E, v_0, \ell)$ where role successors are partitioned into distinctness classes, an *identification* on T is an equivalence relation $\sim$ on V such that $v_1 \sim v_2$ implies that

- there are $u_1, u_2 \in V$ and a role r such that v_1 is an r-successor of u_1, v_2 is an r-successor of u_2, and $u_1 \sim u_2$;
- if $v_1 \neq v_2$, then v_1, v_2 do not belong to the same distinctness class.

Any identification $\sim$ on T induces a description tree $T/\!\sim$ whose nodes are the $\sim$-equivalence classes $[v]_\sim := \{u \in V \mid u \sim v\}$, whose root is $[v_0]_\sim$, and whose edges and node labels are defined as follows:

$$E_\sim := \{([u]_\sim, r, [v]_\sim) \mid \text{there is } u' \in [u]_\sim, v' \in [v]_\sim \text{ such that } (u', r, v') \in E\},$$
$$\ell_\sim([u]_\sim) := \bigcup_{u' \in [u]_\sim} \ell(u').$$

For example, the $\mathcal{EL}^{(n)}$-description tree T_C corresponding to $C = \exists r.A \sqcap \exists r.(B, B)$ is depicted on the left-hand side of Fig. 4, where the r-successors of x_1 are partitioned into the distinctness classes $\{x_2\}, \{x_3, x_4\}$. There are three different identifications: the identity relation, the relation where in addition $x_2 \sim x_3$, and the relation where in addition $x_2 \sim x_4$. The $\mathcal{EL}^{(n)}$-description tree induced by the identity relation is T_C itself, whereas the trees induced by the other two identifications are isomorphic to the tree depicted on the right-hand side of Fig. 4. Obviously, there is an embedding of the $\mathcal{EL}^{(n)}$-description tree T_D corresponding to $D = \exists r.(A, B)$ into each of these two trees.

Theorem 5. *Let C, D be (unrestricted) $\mathcal{EL}^{(n)}$-concept descriptions and T_C, T_D the corresponding description trees. Then $C \sqsubseteq D$ iff for every identification $\sim$ on T_C there exists an embedding from T_D into $T_C/\sim$.*

This theorem yields an NP-algorithm for testing *non*-subsumption of unrestricted $\mathcal{EL}^{(n)}$-concept descriptions: guess in non-deterministic polynomial time an identification $\sim$ of T_C, and then check in polynomial time (by a simple adaptation of the algorithm described in Section 5) whether there is an embedding from T_D into $T_C/\sim$.

Corollary 4. *The subsumption problem for (unrestricted) $\mathcal{EL}^{(n)}$-concept descriptions is in coNP.*

Disjointness statements The characterization of subsumption between (unrestricted) $\mathcal{EL}^{(n)}$-concept descriptions given in Theorem 5 can easily be extended to deal with disjointness statements. In fact, the only thing that must be changed is the definition of an identification: we must additionally require that $u \sim v$ implies $\{P, Q\} \not\subseteq \ell(u) \cup \ell(v)$ for all $\mathit{dis}(P, Q)$ in $\mathcal{D}$. With this new notion of an identification, Theorem 5 also holds w.r.t. a set of disjointness statements $\mathcal{D}$. This shows that the subsumption problem for (unrestricted) $\mathcal{EL}^{(n)}$-concept descriptions w.r.t. disjointness statements is in coNP. In the presence of disjointness statements, we can also show the matching hardness result.

Corollary 5. *The subsumption problem for (unrestricted) $\mathcal{EL}^{(n)}$-concept descriptions w.r.t. disjointness statements is coNP-complete.*

The hardness result can be shown by a reduction of *graph 3-colorability* to non-subsumption.[6] A given undirected graph $G = (V, E)$ is 3-colorable iff there is a mapping $f : V \longrightarrow \{1, 2, 3\}$ such that $\{u, v\} \in E$ implies $f(u) \neq f(v)$. It is well-known (see [12]) that the 3-colorability problem, i.e., the question whether a given graph is 3-colorable, is NP-complete.

Let $G = (V, E)$ be an undirected graph with n vertices, i.e., $V = \{v_1, \ldots, v_n\}$. Without loss of generality we assume that this graph has no loops, i.e., $\{u, v\} \in E$ implies $u \neq v$. Let $A_1, \ldots, A_n$ be concept names. The graph $G = (V, E)$ is represented by the set of disjointness statements

$$\mathcal{D}_G := \{\mathit{dis}(A_i, A_j) \mid \{v_i, v_j\} \in E\}.$$

Let $C := \exists r.A_1 \sqcap \ldots \sqcap \exists r.A_n$ and $D := \exists r.(\top, \top, \top, \top)$. In [5], it is shown that C is *not* subsumed by D w.r.t. $\mathcal{D}_G$ iff G is 3-colorable.

7 Related and future work

Polynomiality of the subsumption problem in $\mathcal{EL}$ was shown in [4] as a by-product of the characterization of subsumption via the existence of homomorphisms between the corresponding description trees. This result can also be

[6] The idea underlying this reduction was suggested by an anonymous reviewer.

obtained as a consequence of the fact that the containment problem $Q_1 \subseteq Q_2$ for conjunctive queries is polynomial if Q_2 is acyclic [25, 20]. Since it is easy to see that $\mathcal{EL}^{(n)}$-concept descriptions can be expressed by acyclic conjunctive queries with disequations [17], one might conjecture that polynomiality of subsumption in $\mathcal{EL}^{(n)}$ follows from the corresponding result for acyclic conjunctive queries with disequations. This is not true, however. In fact, the containment problem for conjunctive queries becomes considerably harder if disequations (i.e., atoms of the form $x \neq y$ for variables x, y) are allowed to occur in the conjunctive queries. For general conjunctive queries with disequations, the containment problem is Π_2^p-complete rather than NP-complete as in the case of conjunctive queries without disequations. Surprisingly, the problem remains Π_2^p-complete if Q_2 is restricted to being acyclic [17]. And even if both queries contain only disequations (and no database predicates), it is not hard to show by a reduction of 3-colorability to non-containment that the containment problem is coNP-hard. Thus, the polynomiality results shown in the present paper does *not* follow from known results for containment of conjunctive queries with disequations.

In [8], it was shown that subsumption in $\mathcal{EL}$ remains polynomial even in the presence of GCIs, and this result was recently extended to a DL extending $\mathcal{EL}$ by several other interesting constructors [1]. Unfortunately, the results in [1] imply that subsumption in $\mathcal{EL}^{(n)}$ becomes ExpTime-hard in the presence of GCIs.

The most interesting topics for future research are, on the one hand, to show that the exponential translation from $\mathcal{EL}^{(n)}\mathcal{C}$ into $\mathcal{ALCQ}$ given in Section 3 is optimal, i.e., to prove that there is no polynomial translation. On the other hand, the exact complexity of subsumption between *unrestricted* $\mathcal{EL}^{(n)}$-concept descriptions is not yet known. The best complexity upper-bound that we currently have is coNP (see Corollary 4). We conjecture that the problem is coNP-hard, but have not yet found an appropriate reduction from a coNP-complete problem.
