

## COMPLEXITY THEORY

**Lecture 20: Circuits and Parallel Computation** 

Markus Krötzsch

**Knowledge-Based Systems** 

TU Dresden, 10th Jan 2018

# What is Efficiently Parallelisable?

#### **Experience suggests:**

Some problems can be solved efficiently in parallel, while others can not.

How could this be shown?

#### Intuitive definition:

A problem has an efficient parallel algorithm if it can be solved for inputs of size n

- in polylogarithmic time, i.e., in time  $O(\log^k n)$  for some  $k \ge 0$ ,
- using a computer with a polynomial number of parallel processors, i.e.,  $O(n^d)$  processors for some  $d \ge 0$ .

**Note:** Using  $O(n^d)$  processors efficiently requires a massively parallel algorithm. However, one could always use fewer processors (each taking on more work), possibly leading to a proportional increase in time.

The hard bit in parallelisation is to utilise many processors effectively – reducing to fewer processors is easy.

Modelling Parallelism With Circuits

Markus Krötzsch, 10th Jan 2018 Complexity Theory

slide 2 of 22

# Modelling Parallel Computation

What kind of "parallel computer" do we mean here?

- (1) How do processors communicate?
- (2) What can a processor do in one step?
- (3) How are processors synchronised?

Detailed answer: define Parallel Random Access Machine (PRAM)

#### Our answer:

Details are not critical as long as we can make some general assumptions:

- (1) Every processor can send a message to any other processor in  $O(\log n)$  time
- (2) In one step, each processors can perform one Boolean operation on "a few" bits, say  $O(\log n)$
- (3) Processor steps are synched with a global clock

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 3 of 22 Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 4 of 22

### Modelling Parallel Computation in Circuits

Simple PRAM computations can be mapped to Boolean circuits (with some extra circuitry for executing more operations or for modelling message passing)

Circuits as models for parallel computation:

- circuit gates can operate in parallel they only depend on their inputs
- the time needed to evaluate a circuit depends on its depth, not size
   (depth = longest distance from an input to an output node)

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 5 of 22

# Small-Depth Circuits

Small depth = short (parallel) time

However: Every Boolean function can be computed by depth  $O(\log n)$  circuits using  $O(n2^n)$  gates (exercise)

Hence, to capture "efficient parallel computation", we also restrict the size:

**Definition 20.1:** For  $k \ge 0$ , we define  $NC^k$  to be the class of all problems that can be solved by a circuit family  $C = C_1, C_2, C_3, \ldots$  such that

- the depth of  $C_n$  is bounded by  $O(\log^k n)$ , and
- there is some  $d \ge 0$  so that the size of  $C_n$  is bounded by  $O(n^d)$  (in other words:  $NC^k \subseteq P_{/poly}$ ).

(NC is for "Nick's class", named in honour of Nicholas Pippenger, who studied such circuits, by Stephen Cook.)

### **Example: Generalised AND**

The function that tests if all inputs are 1 can be encoded by combining binary AND gates:

### **Alternating Circuits**

Different complexity classes are obtained when allowing generalised Boolean gates with many inputs:

slide 6 of 22

**Definition 20.2:** An AND gate with unbounded fan-in is a gate that computes a generalised AND function over an arbitrary number  $n \ge 2$  of inputs. OR gates with unbounded fan-in are defined similarly.

For  $k \ge 0$ , we define  $AC^k$  exactly like  $NC^k$  but allowing circuits to use gates with unbounded fan-in.

**Example 20.3:** Generalised AND is in NC<sup>1</sup> and in AC<sup>0</sup>.

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 7 of 22 Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 8 of 22

# The NC Hierarchy

The classes  $NC^k$  and  $AC^k$  form a hierarchy:

- if  $i \le j$  then  $NC^i \subseteq NC^j$  (obvious)
- if  $i \le j$  then  $AC^i \subseteq AC^j$  (obvious)
- $NC^i \subseteq AC^i$  (obvious)
- $AC^i \subseteq NC^{i+1}$  (since generalised AND and OR can be replaced with  $O(\log n)$  bounded fan-in gates as in our example)

The limit of this hierarchy is defined as  $NC = \bigcup_{k \ge 0} NC^k$  so we get:

$$AC^0 \subseteq NC^1 \subseteq AC^1 \subseteq \cdots \subseteq NC^k \subseteq AC^k \subseteq NC^{k+1} \subseteq \cdots NC^k$$

Note: NC<sup>0</sup> is not a very useful class, as those circuits cannot process the whole input

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 9 of 22

# Example: Parity is in NC<sup>1</sup>

However, we also have the following major result (without proof):

**Theorem 20.4 (see Arora/Barak, Chapter 14): Parity** is not in  $AC^0$ , and therefore  $AC^0 \subseteq NC^1$ .

Uniform vs. Non-uniform

Recall: a circuit family is uniform if it can be computed by a (restricted form of) Turing machine

- Our definitions of NC<sup>k</sup> and AC<sup>k</sup> do not require uniformity
- It is common to define uniform NC<sup>k</sup> and uniform AC<sup>k</sup> using logspace-uniformity (or even more restricted forms of uniformity)
- Clearly: uniform  $NC^k \subseteq NC^k$  and uniform  $AC^k \subseteq AC^k$

**Convention:** For the rest of this lecture, we restrict to (logspace) uniform versions of  $NC^k$  and  $AC^k$ .

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 10 of 22

### Example: FOL model checking

#### FOL MODEL CHECKING

Input: First-order sentence  $\varphi$ ; finite first-order structure  $\mathcal{I}$ 

Problem: Is  $\varphi$  satisfied by I?

We showed that this problem is PSpace-complete.

It turns out that this complexity is caused by the formula, not by the model:

#### FOL Model Checking for $\varphi$

Input: A finite first-order structure *I*.

Problem: Is  $\varphi$  satisfied by  $\mathcal{I}$ ?

Theorem 20.5 (see course Database Theory, Summer 2018, TU Dresden): For any first-order sentence  $\varphi$ , FOL Model Checking for  $\varphi$  is in AC<sup>0</sup>.

Markus Krőtzsch, 10th Jan 2018 Complexity Theory slide 11 of 22 Markus Krőtzsch, 10th Jan 2018 Complexity Theory slide 12 of 22

### Relationships to Other Complexity Classes (1)

Using the assumption of uniformity, we can solve circuit complexity problems by (1) computing the circuit and (2) evaluating it.

The following are not hard to show:

Theorem 20.6 (Sipser, Theorem 10.41):  $NC \subseteq P$ 

Theorem 20.7 (Sipser, Theorem 10.39):  $NC^1 \subseteq L$ 

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 13 of 22

# P-Completeness

## Relationships to Other Complexity Classes (2)

Conversely, some known classes are also subsumed by NC:

Theorem 20.8:  $NL \subseteq AC^1$ 

#### **Proof notes:**

General proof idea: (1) construct a "generalised" configuration graph for an NL machine (a graph that describes all possible configuration graphs for inputs of a given length, using transitions that depend on the actual input that is given); (2) check reachability of the goal state in this graph (basically by repeated matrix multiplication in the reachability matrix).

We do not give a proof here. Sipser (Theorem 10.40) sketches the proof for  $NL \subseteq NC^2$ ; the proof for  $NL \subseteq AC^1$  is the same but also uses that the depth is only logarithmic if we can use unbounded fan-in gates.

We therefore obtain the following picture:

$$\mathsf{AC}^0 \subset \mathsf{NC}^1 \subset \mathsf{L} \subset \mathsf{NL} \subset \mathsf{AC}^1 \subset \mathsf{NC}^2 \subset \cdots \; \mathsf{NC} \subset \mathsf{P}$$

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 14 of 22

# The Limits of Parallel Computation

NC defines a hierarchy of efficiently parallelisable problems in P

Are all problems in P efficiently parallelisable? Nobody knows.

#### State of the art:

- It is not known if NC ≠ P or not
- It is not even known if NC<sup>1</sup> ≠ PH or not
- It is clear that  $AC^0 \neq P$  (since  $AC^0 \subset NC^1$ )
- It is clear that NC ≠ PSpace (exercise: why?)

"Most experts believe that" NC ≠ P

→ if this is true, then some problems in P cannot be parallelised efficiently

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 15 of 22 Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 16 of 22

## P-Complete Problems

#### Recall the definition from Lecture 11:

**Definition 11.7:** A problem  $L \in P$  is complete for P if every other language in P is log-space reducible to L.

If  $NC \neq P$  then P-complete problems are tractable but not efficiently parallelisable and therefore inherently serial.

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 17 of 22

### Propositional Horn Logic

A problem that is closer to artificial intelligence:

- A propositional fact is a formula consisting of a single propositional variable X
- A propositional Horn rule is a formula of the form  $X_1 \wedge X_2 \rightarrow X_3$
- A propositional Horn theory is a set of propositional Horn rules and facts

The semantics of propositional Horn theories is defined as usual for propositional logic.

#### PROP HORN ENTAILMENT

Input: A propositional Horn theory T and a propo-

sitional variable X

Problem: Does *T* entail *X* to be true?

### Circuit Evaluation is P-complete

#### CIRCUIT VALUE

Input: A Boolean Circuit *C* with one output, and an

input word  $w \in \{0, 1\}^n$ 

Problem: Does *C* return 1 on this input?

#### Theorem 20.9: CIRCUIT VALUE is P-complete.

**Proof:** Membership is easy. For completeness, we reduce the word problem of polynomially time-bounded Turing machines. A circuit for this problem was constructed in the previous lecture for Theorem 19.7. This circuit family is logspace-uniform (as already remarked in Theorem 19.13), so we get a logspace-reduction.

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 18 of 22

# Propositional Horn Logic is P-Complete

#### Theorem 20.10: Prop Horn Entailment is P-complete.

**Proof sketch:** One can give a direct Turing machine encoding:

- We use propositional variables to represent configurations as for Cook-Levin
- We encode TM behaviour directly, e.g., for transitions  $\langle q,\sigma\rangle \mapsto \langle q',\sigma',d\rangle$  we can use rules like  $Q_{q,t} \wedge P_{i,t} \wedge S_{i,\sigma,t} \to Q_{q',t+1} \wedge P_{i+d,t+1} \wedge S_{i,\sigma',t+1}$  (for all times t and positions t)
- We do not need rules that forbid inconsistent configurations (two states at once etc.): Horn
  logic has a least model, and we don't need to worry about other models when checking
  entailment
- Disjunctive acceptance conditions ("accepts if there is some time point at which is reaches an accepting state") can be encoded by many implications (one for each case) without "real" disjunctions

For details, see Theorem 4.2 in Dantsin, Eiter, Gottlob, Voronkov: Complexity and expressive power of logic programming (link). ACM Computing Surveys, 2001.

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 19 of 22 Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 20 of 22

## Complexity vs. Runtime

#### Horn logic is P-complete:

- One of the hardest problems in P
- Inherently non-parallelisable

#### However:

- Prop Horn Entailment can be decided in linear time [Dowling/Gallier, 1984]
- This does not imply that all problems in P have linear time algorithms

Markus Krötzsch, 10th Jan 2018 Complexity Theory slide 21 of 22

# Summary and Outlook

Small-depth circuits can be used to model efficient parallel computation

NC defines a hierarchy of problems below P:

$$\mathsf{AC}^0 \subset \mathsf{NC}^1 \subseteq \mathsf{L} \subseteq \mathsf{NL} \subseteq \mathsf{AC}^1 \subseteq \mathsf{NC}^2 \subseteq \cdots \ \mathsf{NC} \subseteq \mathsf{P}$$

P-complete problems, such as Horn logic entailment, are believed not to be efficiently parallelisable.

#### What's next?

- Randomness
- Summary
- Examinations
