RDFS Rule-based Reasoning

Sebastian Rudolph

RDFS Rule-based Reasoning

RDFS Rule-based Reasoning

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Constituents of Rules

- basic elements of rules are atoms
 - ground atoms without free variables
 - non-ground atoms with free variables

What are Rules?

① logic rules (fragments of predicate logic):

- $F \rightarrow G$ equivalent to $\neg F \vee G$
- logical extension of knowledge base \rightsquigarrow static
- open world
- declarative (describing)

What are Rules?

① logic rules (fragments of predicate logic):

- $F \rightarrow G$ equivalent to $\neg F \vee G$
- logical extension of knowledge base \rightsquigarrow static
- open world
- declarative (describing)

② procedural rules (e.g. production rules):

- “If X then Y else Z”
- executable commands \rightsquigarrow dynamic
- operational (meaning = effect caused when executed)

What are Rules?

1 logic rules (fragments of predicate logic):

- $F \rightarrow G$ equivalent to $\neg F \vee G$
- logical extension of knowledge base \rightsquigarrow static
- open world
- declarative (describing)

2 procedural rules (e.g. production rules):

- “If X then Y else Z”
- executable commands \rightsquigarrow dynamic
- operational (meaning = effect caused when executed)

3 logic programming et al. (e.g. PROLOG, F-Logic):

- `man(X) :- person(X) AND NOT woman(X)`
- approximation of logical semantics with operational aspects,
built-ins are possible
- often closed-world
- semi-declarative

Predicate Logic as a Rule Language

- rules as implication formulae in predicate logic:

$$\underbrace{H}_{\text{head}} \leftarrow \underbrace{A_1 \wedge A_2 \wedge \dots \wedge A_n}_{\text{body}}$$

Predicate Logic as a Rule Language

- rules as implication formulae in predicate logic:

$$\underbrace{H}_{\text{head}} \leftarrow \underbrace{A_1 \wedge A_2 \wedge \dots \wedge A_n}_{\text{body}}$$

↔ semantically equivalent to disjunction:

$$H \vee \neg A_1 \vee \neg A_2 \vee \dots \vee \neg A_n$$

- implications often written from right to left (\leftarrow or $:$)
- constants, variables and function symbols allowed
- quantifiers for variables are often omitted:
free variables are often understood as universally quantified
(i.e. rule is valid for all variable assignments)

Rules – Example

Example:

$$\text{hasUncle}(x, z) \leftarrow \text{hasParent}(x, y) \wedge \text{hasBrother}(y, z)$$

- we use short names (hasUncle) instead of IRIs like <http://example.org/Example#hasUncle>
- we use x,y,z for variables

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Lloyd-Topor Transformation

- multiple heads in atoms are usually understood as conjunction

$$H_1, H_2, \dots, H_m \leftarrow A_1, A_2, \dots, A_n$$

equivalent to

$$H_1 \leftarrow A_1, A_2, \dots, A_n$$
$$H_2 \leftarrow A_1, A_2, \dots, A_n$$

...

$$H_m \leftarrow A_1, A_2, \dots, A_n$$

- such a rewriting is also referred to as Lloyd-Topor transformation

Disjunctive Rules

- some rule formalisms allow for disjunction
 - ~ several atoms in the head are conceived as alternatives:

$$H_1, H_2, \dots, H_m \leftarrow A_1, A_2, \dots, A_n$$

equivalent to

$$H_1 \vee H_2 \vee \dots \vee H_m \leftarrow A_1 \wedge A_2 \wedge \dots \wedge A_n$$

equivalent to

$$H_1 \vee H_2 \vee \dots \vee H_m \vee \neg A_1 \vee \neg A_2 \vee \dots \vee \neg A_n$$

~ (not considered here)

Kinds of Rules

names for “rules” in predicate logic:

- clause: disjunction of atomic and negated atomic propositions
 - $\text{Woman}(x) \vee \text{Man}(x) \leftarrow \text{Person}(x)$

Kinds of Rules

names for “rules” in predicate logic:

- clause: disjunction of atomic and negated atomic propositions
 - $\text{Woman}(x) \vee \text{Man}(x) \leftarrow \text{Person}(x)$
- Horn clause: clause with at most one non-negated atom
 - $\leftarrow \text{Man}(x) \wedge \text{Woman}(x)$
 - ~≈ “integrity constraints”

Kinds of Rules

names for “rules” in predicate logic:

- clause: disjunction of atomic and negated atomic propositions
 - $\text{Woman}(x) \vee \text{Man}(x) \leftarrow \text{Person}(x)$
- Horn clause: clause with at most one non-negated atom
 - $\leftarrow \text{Man}(x) \wedge \text{Woman}(x)$
 - ~≈ “integrity constraints”
- definite clause: Horn clause with exactly one non-negated atom
 - $\text{Father}(x) \leftarrow \text{Man}(x) \wedge \text{hasChild}(x, y)$

Kinds of Rules

names for “rules” in predicate logic:

- clause: disjunction of atomic and negated atomic propositions
 - $\text{Woman}(x) \vee \text{Man}(x) \leftarrow \text{Person}(x)$
- Horn clause: clause with at most one non-negated atom
 - $\leftarrow \text{Man}(x) \wedge \text{Woman}(x)$
 - ~~ “integrity constraints”
- definite clause: Horn clause with exactly one non-negated atom
 - $\text{Father}(x) \leftarrow \text{Man}(x) \wedge \text{hasChild}(x, y)$
- fact: clause containing just one non-negated atom
 - $\text{Woman}(\text{gisela})$

Kinds of Rules

Rules may also contain function symbols:

$$\begin{aligned} \text{hasUncle}(x, y) &\leftarrow \text{hasBrother}(\text{mother}(x), y) \\ \text{hasFather}(x, \text{father}(x)) &\leftarrow \text{Person}(x) \end{aligned}$$

- ~~ new elements are dynamically generated
- ~~ not considered here
- ~~ see logic programming

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Datalog

Horn rules without function symbols \rightsquigarrow Datalog rules

- logical rule language, originally basis of deductive databases
- knowledge bases (“programs”) consisting of Horn clauses without function symbols
- decidable
- efficient for big datasets, combined complexity ExpTime
- a lot of research done in the 1980s

Datalog as Extension of the Relation Calculus

Datalog can be conceived as Extension of the relation calculus by recursion

$$\begin{aligned} T(x, y) &\leftarrow E(x, y) \\ T(x, y) &\leftarrow E(x, z) \wedge T(z, y) \end{aligned}$$

~~ computes the transitive closure (T) of the binary relation E , (e.g. if E contains the edges of a graph)

- a set of (ground) facts is also called an instance

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Semantics of Datalog

three different but equivalent ways to define the semantics:

- model-theoretically
- proof-theoretically
- via fixpoints

Model-theoretic Semantics of Datalog

rules are seen as logical sentences:

$$\forall x, y. (T(x, y) \leftarrow E(x, y))$$

$$\forall x, y. (T(x, y) \leftarrow E(x, z) \wedge T(z, y))$$

- not sufficient to uniquely determine a solution
 - ~ \rightarrow interpretation of T has to be minimal

Model-theoretic Semantics of Datalog

in principle, a Datalog rule

$$\rho: R_1(u_1) \leftarrow R_2(u_2), \dots, R_n(u_n)$$

represents the FOL sentence

$$\forall x_1, \dots, x_n. (R_1(u_1) \leftarrow R_2(u_2) \wedge \dots \wedge R_n(u_n))$$

- x_1, \dots, x_n are the rule's variables and \leftarrow is logical implication
- an instance I satisfies ρ , written $I \models \rho$, if and only if for every instantiation

$$R_1(\nu(u_1)) \leftarrow R_2(\nu(u_2)), \dots, R_n(\nu(u_n))$$

we find $R_1(\nu(u_1))$ satisfied whenever $R_2(\nu(u_2)), \dots, R_n(\nu(u_n))$ are satisfied

Model-theoretic Semantics of Datalog

- an instance I is a model of a Datalog program P , if I satisfies every rule in P (seen as a FOL formula)
- the semantics of P for the input I is the minimal model that contains I (if it exists)
- Question: does such a model always exist?
- If so, how can we construct it?

Proof-theoretic Semantics of Datalog

based on proofs for facts:

given : $E(a, b), E(b, c), E(c, d)$

$$T(x, y) \leftarrow E(x, y) \tag{1}$$

$$T(x, y) \leftarrow E(x, z) \wedge T(z, y) \tag{2}$$

- (a) $E(c, d)$ is a given fact
- (b) $T(c, d)$ follows from (1) and (a)
- (c) $E(b, c)$ is a given fact
- (d) $T(b, d)$ follows from (c), (b) and (2)
- (e) ...

Proof-theoretic Semantics of Datalog

- programs can be seen as “factories” that produce all provable facts (deriving new facts from known ones in a **bottom-up** way by applying rules)
- alternative: **top-down** evaluation; starting from a to-be-proven fact, one looks for lemmata needed for the proof (\rightsquigarrow Resolution)

Proof-theoretic Semantics of Datalog

a fact is provable, if it has a proof, represented by a proof-tree:

Definition

A proof tree for a fact A for an instance I and a Datalog program P is a labeled tree in which

- 1 every node is labeled with a fact
- 2 every leaf is labeled with a fact from I
- 3 the root is labeled with A
- 4 for each internal leaf there exists an instantiation $A_1 \leftarrow A_2, \dots, A_n$ of a rule in P, such that the node is labeled with A_1 and its children with A_2, \dots, A_n

Proof-theoretic Semantics of Datalog

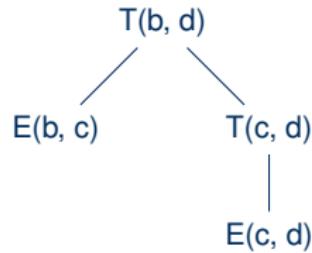

based on proofs for facts:

given : $E(a, b), E(b, c), E(c, d)$

$$T(x, y) \leftarrow E(x, y) \tag{1}$$

$$T(x, y) \leftarrow E(x, z) \wedge T(z, y) \tag{2}$$

- (a) $E(c, d)$ is a given fact
- (b) $T(c, d)$ follows from (1) and (a)
- (c) $E(b, c)$ is a given fact
- (d) $T(b, d)$ follows from (c), (b) and (2)
- (e) ...

Fixpoint Semantics

defines the semantics of a Datalog program as the solution of a fixpoint equation

- procedural definition (iteration until fixpoint reached)
- given an instance I and a Datalog program P , we call a fact A a direct consequence for P and I , if
 - 1 A is contained in I or
 - 2 $A \leftarrow A_1, \dots, A_n$ is the instance of a rule from P , such that
$$A_1, \dots, A_n \in I$$
- then we can define a “direct consequence”-operator that computes, starting from an instance, all direct consequences
- similar to the bottom-up proof-theoretic semantics, but shorter proofs are always generated earlier than longer ones

Semantics of Rules

- compatible with other approaches that are based on FOL (e.g. description logics)
- conjunctions in rule heads and disjunction in bodies unnecessary
- other (non-monotonic) semantics definitions possible
 - well-founded semantics
 - stable model semantics
 - answer set semantics
- for Horn rules, these definitions do not differ
- production rules/procedural rules conceive the consequence of a rule as an action “If-then do”
~~ not considered here

Extensional and Intensional Predicates

- from the database perspective (and opposed to logic programming) one distinguishes facts and rules
- within rules, we distinguish **extensional** and **intensional** predicates
- extensional predicates (also: extensional database – edb) are those not occurring in rule heads (in our example: relation E)
- intensional predicates (also: intensional database – idb) are those occurring in at least one head of a rule (in our example: relation T)
- semantics of a datalog program can be understood as a mapping of given instances over edb predicates to instances of idb predicates

Datalog in Practice

Datalog in Practice:

- several implementations available
- some adaptations for Semantic Web: XSD types, URIs (e.g. → IRIS)

Extensions of Datalog:

- disjunctive Datalog allows for disjunctions in rule heads
- non-monotonic negation (no FOL semantics)

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Evaluating Datalog Programs

- top-down or bottom-up evaluation
- direct evaluation versus compilation into an efficient program
- here:
 - 1 Naïve bottom-up Evaluierung
 - 2 Semi-naïve bottom-up Evaluierung

Reverse-Same-Generation

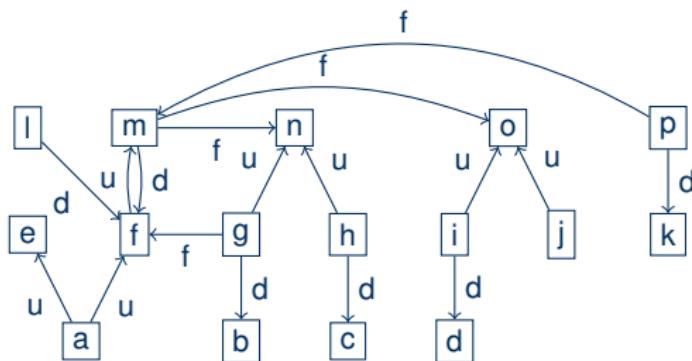

given Datalog programm:

$$\text{rsg}(x, y) \leftarrow \text{flat}(x, y)$$
$$\text{rsg}(x, y) \leftarrow \text{up}(x, x_1), \text{rsg}(y_1, x_1), \text{down}(y_1, y)$$

given data:

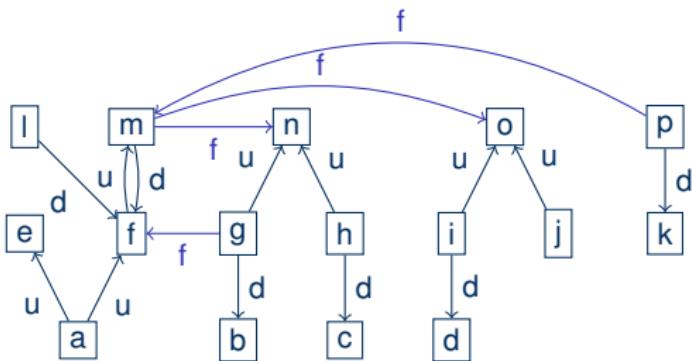

up	flat	down
a e	g f	l f
a f	m n	m f
f m	m o	g b
g n	p m	h c
h n		i d
i o		p k
j o		

Reverse-Same-Generation – Visualization

$$\begin{aligned}
 rsg(x, y) &\leftarrow flat(x, y) \\
 rsg(x, y) &\leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)
 \end{aligned}$$

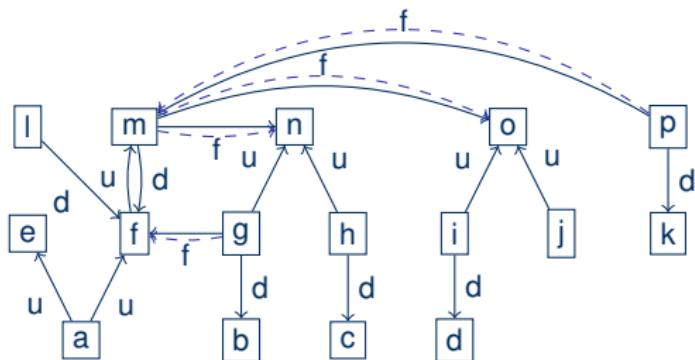

Reverse-Same-Generation – Visualization

$rsg(x, y) \leftarrow flat(x, y)$

$rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

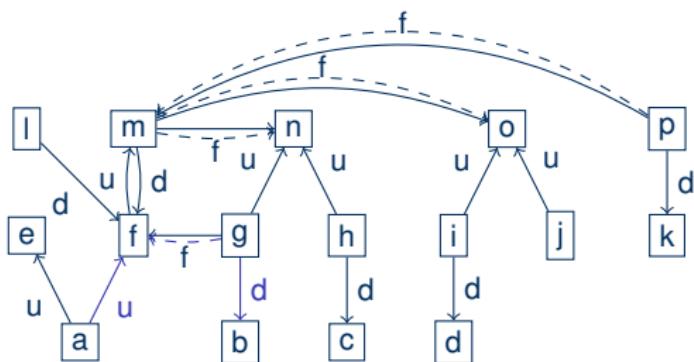

Reverse-Same-Generation – Visualization

$$rsg(x, y) \leftarrow flat(x, y)$$

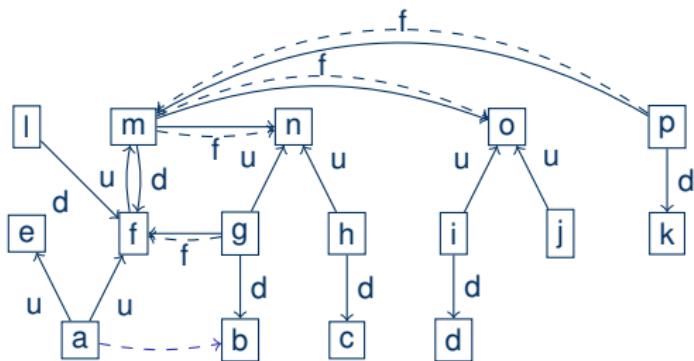

$$rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$$

Reverse-Same-Generation – Visualization

$rsg(x, y) \leftarrow flat(x, y)$
 $rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

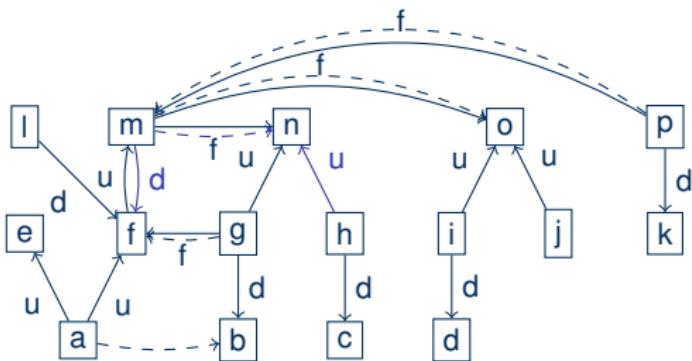

Reverse-Same-Generation – Visualization

$$rsg(x, y) \leftarrow flat(x, y)$$

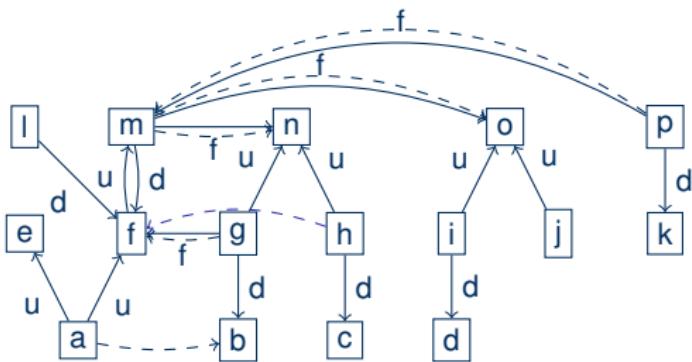

$$rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$$

Reverse-Same-Generation – Visualization

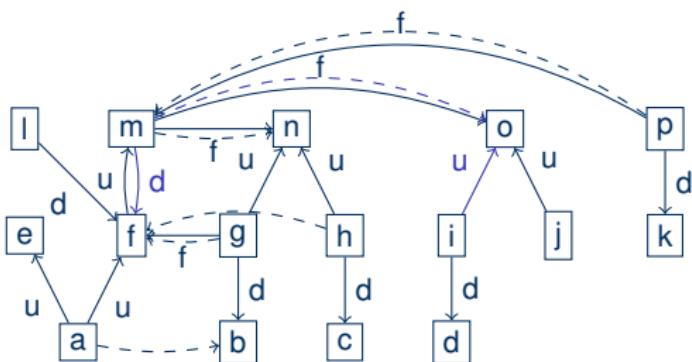

$rsg(x, y) \leftarrow flat(x, y)$
 $rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

Reverse-Same-Generation – Visualization

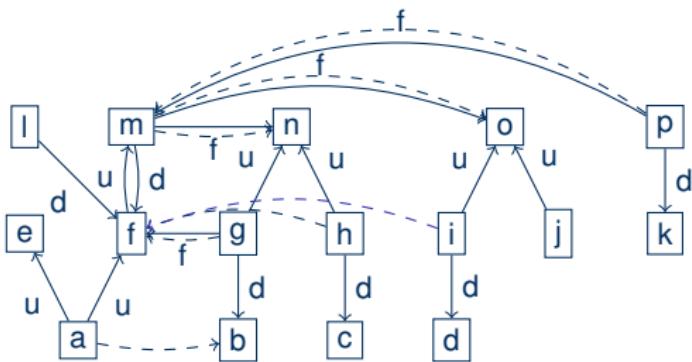

$rsg(x, y) \leftarrow flat(x, y)$
 $rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

Reverse-Same-Generation – Visualization

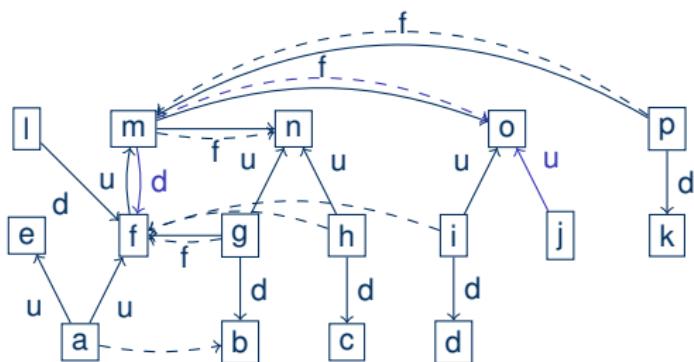

$rsg(x, y) \leftarrow flat(x, y)$
 $rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

Reverse-Same-Generation – Visualization

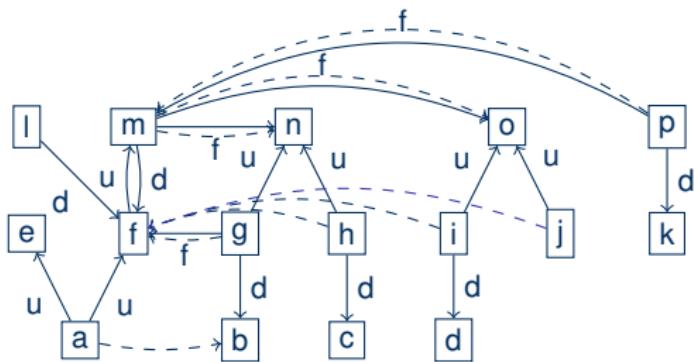

$rsg(x, y) \leftarrow flat(x, y)$
 $rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

Reverse-Same-Generation – Visualization

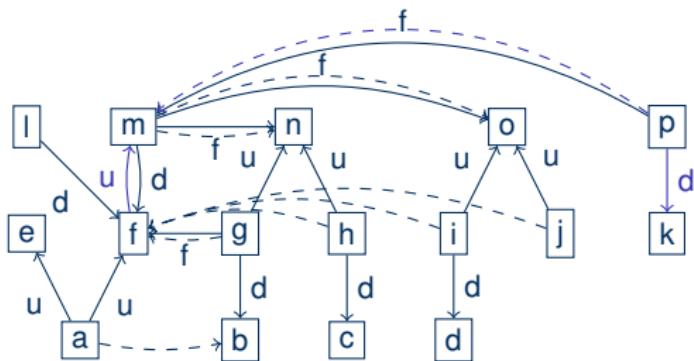

$rsg(x, y) \leftarrow flat(x, y)$
 $rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

Reverse-Same-Generation – Visualization

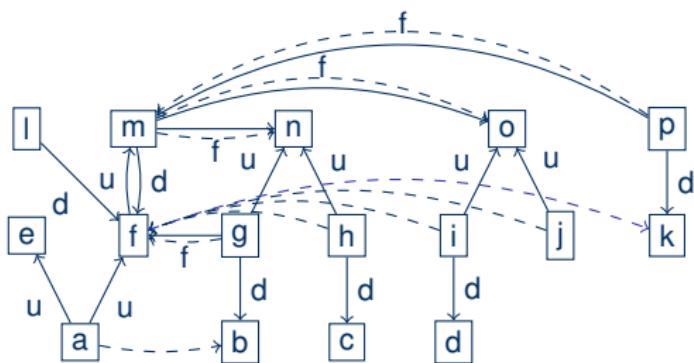

$$\begin{aligned}rsg(x, y) &\leftarrow \text{flat}(x, y) \\rsg(x, y) &\leftarrow \text{up}(x, x_1), rsg(y_1, x_1), \text{down}(y_1, y)\end{aligned}$$

Reverse-Same-Generation – Visualization

$rsg(x, y) \leftarrow flat(x, y)$
 $rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

Reverse-Same-Generation – Visualization

$rsg(x, y) \leftarrow flat(x, y)$

$rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Naïve Algorithm for Computing rsg

$rsg(x, y) \leftarrow flat(x, y)$
 $rsg(x, y) \leftarrow up(x, x_1), rsg(y_1, x_1), down(y_1, y)$

Algorithm 1 RSG

```
rsg :=  $\emptyset$ 
repeat
    rsg := rsg  $\cup$  flat  $\cup$   $\pi_{16}(\sigma_{2=4}(\sigma_{3=5}(up \times rsg \times down)))$ 
until fixpoint reached
```

$$rsg^{i+1} := rsg^i \cup flat \cup \pi_{16}(\sigma_{2=4}(\sigma_{3=5}(up \times rsg \times down)))$$

Level 0: \emptyset

Level 1: $\{(g, f), (m, n), (m, o), (p, m)\}$

Level 2: $\{\text{Level 1}\} \cup \{(a, b), (h, f), (i, f), (j, f), (f, k)\}$

Level 3: $\{\text{Level 2}\} \cup \{(a, c), (a, d)\}$

Level 4: $\{\text{Level 3}\}$

Naïve Algorithm for Evaluating Datalog Programs

- redundant computations (all elements of the preceding level are taken into account)
- on each level, all elements of the preceding level are re-computed
- monotone (rsg is extended more and more)

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Semi-Naïve Algorithm for Computing rsg

focus on facts that have been newly computed on the preceding level

Algorithm 2 RSG'

$$\Delta_{rsg}^1(x, y) := \text{flat}(x, y)$$

$$\Delta_{rsg}^{i+1}(x, y) := \text{up}(x, x_1), \Delta_{rsg}^i(y_1, x_1), \text{down}(y_1, y)$$

- not recursive
- no Datalog program (set of rules is infinite)
- for each input I and Δ_{rsg}^i (the newly computed instances on level i),

$$rsg^{i+1} - rsg^i \subseteq \Delta_{rsg}^{i+1} \subseteq rsg^{i+1}$$

- $\text{RSG}(I)(rsg) = \cup_{1 \leq i} (\Delta_{rsg}^i)$
- less redundancy

An Improvement

But: $\Delta_{rsg}^{i+1} \neq rsg^{i+1} - rsg^i$

e.g.: $(g,f) \in \Delta_{rsg}^2$, $(g,f) \notin rsg^2 - rsg^1$

$\rightsquigarrow rsg(g,f) \in rsg^1$, because $flat(g,f)$,

$\rightsquigarrow rsg(g,f) \in \Delta_{rsg}^2$, because $up(g,n), rsg(m,f), down(m,f)$

- idea: use $rsg^i - rsg^{i-1}$ instead of Δ_{rsg}^i in the second “rule” of RSG'

Algorithm 3 RSG''

$$\Delta_{rsg}^1(x,y) := flat(x,y)$$

$$rsg^1 := \Delta_{rsg}^1$$

$$tmp_{rsg}^{i+1}(x,y) := up(x,x_1), \Delta_{rsg}^i(y_1,x_1), down(y_1,y)$$

$$\Delta_{rsg}^{i+1}(x,y) := tmp_{rsg}^{i+1} - rsg^i$$

$$rsg^{i+1} := rsg^i \cup \Delta_{rsg}^{i+1}$$

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Datalog Rules for RDFS (no Datatypes & Literals)

problem: no strict separation between data and schema (predicates)

$$\frac{a \text{ rdfs:domain } x . \ u \ a \ y .}{u \text{ rdf:type } x .} \text{ rdfs2}$$

$\text{rdf:type}(u, x) \leftarrow \text{rdfs:domain}(a, x) \wedge a(u, y)$

- solution: use a triple predicate

Datalog Rules for RDFS (no Datatypes & Literals)

problem: no strict separation between data and schema (predicates)

$$\frac{a \text{ rdfs:domain } x . \ u \ a \ y .}{u \text{ rdf:type } x .} \text{ rdfs2}$$

$\text{rdf : type}(u, x) \leftarrow \text{rdfs : domain}(a, x) \wedge a(u, y)$

- solution: use a triple predicate

Agenda

- Rules
 - Llyod-Topor Transformation
- Datalog
 - Characterizations of Datalog Program Semantics
- Evaluating Datalog Programs
 - Naïve Evaluation
 - Semi-naïve Evaluation
- Rules for RDFS via a Triple Predicate
- Rules for RDFS via Direct Translation

Datalog Rules for RDFS (no Datatypes & Literals)

$$\frac{a \text{ rdfs:domain } x . \ u \ a \ y .}{u \text{ rdf:type } x .} \text{ rdfs2}$$

$\text{Triple}(u, \text{rdf:type}, x) \leftarrow \text{Triple}(a, \text{rdfs:domain}, x) \wedge \text{Triple}(u, a, y)$

- usage of just one predicate reduces optimization potential
- all (newly derived) triples are potential candidates for any rule
- rules change when the data changes, no separation between schema and data

Datalog Rules for RDFS (no Datatypes & Literals)

- solution 2: introduce specific predicates

$$\frac{a \text{ rdfs:domain } x . \ u \ a \ y .}{u \text{ rdf:type } x .} \text{ rdfs2}$$

`type(u,x) ← domain(a,x) ∧ rel(u,a,y)`

Axiomatic Triples as Facts

```
type(rdf:type, rdf:Property)
